**ABSTRACT**

**Aims:** To evaluate the analgesic and anti-inflammatory effects of ethanolic bark extract of *Plumeria rubra* on experimental animal models.

**Study design:** Assessment of antinociceptive and anti-inflammatory activity.

**Place and Duration of Study:** Department of Pharmacy, North South University, Dhaka, Bangladesh, between January 2011 and June 2011.

**Methodology:** The analgesic activity was evaluated by hot plate, acetic acid induced writhing and formalin induced writhing method in Swiss Albino mice divided into 4 different groups (control, standard diclofenac sodium and extract at two different doses of 250 and 500 mg/kg BW). The extract was also investigated for the anti-inflammatory effect on Long Evans rats using carrageenan induced rat paw edema method. For anti-inflammatory study, 24 rats were divided into 4 different groups each receiving either distilled water, standard drug or the extract at the doses of 250 and 500 mg/kg BW.

**Results:** Phytochemical analysis of the extract revealed the presence of tannins, alkaloids, flavonoids and terpenoids. The extract elicited a highly significant (p<0.001) analgesic activity in a dose dependent manner on hot plate method, acetic acid induced writhing test and also on both the early and late phases of formalin test at the doses employed. In the hot plate method, the extract increased the reaction time of heat sensation to 60.81% and 66.52% at the doses of 250 and 500 mg/kg BW respectively while that of the standard drug was 57.40% at the 3rd hour of study. In acetic acid induced writhing test, the percent inhibition of writhing response by the extract was 62.87% and 70.66% at 250 and 500 mg/kg doses respectively (p<0.001) which were even better than the standard drug diclofenac sodium (50.30%). The extract also significantly inhibited the licking response at the dose of 500 mg/kg in both the early phase (55.11%, p<0.01) and the late phase (66.43%, p<0.01) of formalin test while the standard drug inhibited by 52.27% and 72.03%, respectively. The oral administration of the extract significantly (p<0.001) inhibited inflammatory response induced
by carrageenan in a dose dependent fashion. The most prominent inhibition of 61.68% (250 mg/kg) and 73.65% (500 mg/kg) were observed at the 4th hour of study. **Conclusion:** The central and peripheral analgesic as well as anti-inflammatory effect of the ethanolic bark extract of *P. rubra* may be due to the presence of various chemical constituents specially flavonoids, tannins, alkaloids or terpenoids. These experimental findings would further establish the scientific basis of the traditional uses of the plant in the management and/or control of pain as well as inflammatory conditions.

**Keywords:** Plumeria rubra; medicinal plant; phytochemical screening; analgesic; anti-inflammatory; acetic acid; formalin; carrageenan.

**1. INTRODUCTION**

The medicinal plants find applications in various important sectors like in pharmaceutical, cosmetic, agricultural and food industry. The use of the medicinal herbs for curing diseases has been documented in history of all civilizations. The efficacy of some herbal products is beyond doubt, the most recent examples being *Silybum marianum* (silymarin), *Artemisia annua* (artemisinin) and *Taxus baccata* (taxol). With onset of scientific research in herbals, it has become clearer that the medicinal herbs have a potential in today’s synthetic era, as numbers of medicines are becoming resistant. According to one estimate only 20% of the plant flora has been studied and 60% of synthetic medicines owe their origin to plants (Ayurvedaherbs, 2005). Moreover, in some Asian and African countries, 80% of the population depends on traditional medicine for primary health care (WHO, 2008). Due to its importance and availability, herbs are staging a comeback and herbal ‘renaissance’ is happening all over the globe. The herbal products today symbolize safety in contrast to the synthetics that are regarded as unsafe to human and environment. More than 30% of the entire plant species, at one time or another, was used for medicinal purposes (Joy et al., 1998).

Inflammation is a pathophysiological response of mammalian tissues to a variety of hostile agents including infectious organisms, toxic chemical substances, physical injury or other noxious stimuli leading to local accumulation of plasma fluid and blood cells (Sobota et al., 2000; Medzhitov, 2010). Although it is a defense mechanism, the complex events and mediators involved the inflammatory reaction can induce, maintain or aggravate many diseases (Sosa et al., 2002) and so it has become the focus of global scientific research. Anti-inflammatory and analgesic therapy is dominated by opioids and non steroidal anti-inflammatory drugs (NSAIDs) but both classes of drugs produce serious side effects (Park et al., 2004). The search for pharmacological agents to overcome these shortcomings has become a major goal in pain research. Medicinal plants are considerably useful and economically essential. They contain active constituents that are used in the treatment of many human diseases. The effectiveness of phytochemicals in the treatment of various diseases may lie in their analgesic and anti-inflammatory effects (Akinmoladun et al., 2007).

*Plumeria rubra* (Family - Apocynaceae) is a deciduous plant species belonging to the genus *Plumeria* commonly known as Red Frangipani, Common Frangipani, Temple Tree, or simply Plumeria (Könemann, 2004). They are native to Mexico, Central America, the Caribbean and South America as far south as Brazil but have been spread throughout the world's tropics including Bangladesh (GRIN, 2009). It grows as a spreading tree with crooked trunk and rough bark, swollen branches leafy at the tips, elongated alternate leaves, and large fragrant flowers of shades of pink, white and yellow. Previous phytochemical studies of the plant have shown the presence of oleanene type triterpenes, plumeric acid and methyl ether plumerates. The bark has been reported to contain bitter glycosides, plumeride, plumeric
acid, amyrin and fulvoplumierin. The plant is used traditionally in rheumatism, gum troubles, toothache, diarrhea, gonorrhea and also as purgative (Ghani, 2003). However, to our knowledge, there is no scientific report on the verification of the use of the plant in the treatment of rheumatism. Inflammation has been reported to be the main pathological characteristic of rheumatism such as rheumatoid arthritis (Zhang et al., 2008; Rewatkar et al., 2010). On the other hand, pain is a common symptom of rheumatism and antinociceptive effects of successful painkillers are considered to be crucial in a variety of species and pain tests (McIntosh et al., 2009; Pan et al., 2010). Therefore, as a part of our continuing studies on the various medicinal plants of Bangladesh (Das et al., 2007; Hannan et al., 2011; Das et al., 2011), the present study was undertaken to explore any possible antinociceptive and anti-inflammatory potential of the ethanolic bark extract of *Plumeria rubra* in mice and rats so as to justify the traditional uses of this plant in folklore medicine.

2. MATERIALS AND METHODS

2.1 Collection and identification of the plant material

Fresh bark of *P. rubra* was collected from Jahangirnagar University residential area, Savar, Dhaka, Bangladesh. The plant was identified by the experts of Bangladesh National Herbarium (BNH). The specimen was preserved in BNH and Department of Pharmacy, North South University, Bangladesh and it has been assigned the accession number of DACB 35518.

2.2 Preparation of extracts

The plant bark was kept under sunshade for 5 days and then heated in an oven at below 40°C for 24 hours to be fully dried. After drying, it was ground thoroughly to powdered form and was stored in cold conditions in an airtight container. The powder obtained was extracted via the method of cold extraction using ethanol and then kept for a period of 5 days accompanying occasional shaking and stirring. The whole mixture then underwent a coarse filtration by a piece of clean, white cotton material followed by a second filtration through whatman filter paper. The filtrate (ethanol extract) obtained was evaporated by rotary evaporator (Bibby RE-200, Sterilin Ltd., UK) at 5 to 6 rpm and at 68°C temperature. It rendered a gummy concentrate of dark greenish black colour that was designated as crude ethanolic extract. The extract was finally dried by freeze drier and preserved.

2.3 Animal used

Young Swiss-Albino mice aged about 4-5 weeks with average weight of 25-35 gm and adult Long Evans Rats of either sex having average weight of 100-130 gm were used for the experiment and maintained in the animal house of the Department of Pharmacy, North South University for acclimation. The animals were originally obtained from International Centre for Diarrhoeal Disease Research, Bangladesh (*ICDDR*, *B*). They were housed in standard cages under standard environmental conditions of room temperature at 24 ± 1°C and 55-65% relative humidity with 12 hour dark light cycle and provided with standard food for rodents and water *ad libitum*. All experiments involving animals were conducted according to the UK Home Office regulations (UK Animals Scientific Procedures Act 1986) and the ‘Principles of Laboratory Animal Care’ (National Institutes of Health publication no. 86-23, revised 1985).

2.4 Method for phytochemical analysis
The freshly prepared extract of *P. rubra* was qualitatively tested for the presence of chemical constituents. Qualitative phytochemical tests for the identification of alkaloids, flavonoids, steroids, gum and carbohydrates, saponins, tannins and terpenoids were carried out for the extract by the method described previously (Harborne, 1998; Siddiqui et al., 2009).

2.5 Method for the evaluation of analgesic effect

2.5.1 Hot plate test

The hot-plate test (Hot/Cold Plate Model-35100-001, UGO Basile, Italy) was employed for measurement of analgesic activity as previously described by Lanfers *et al.* and modified by Ojewole (Lanhers *et al.*, 1992; Ojewole, 2004). The temperature was regulated at 55° ± 1°C. Mice of either sex were divided into four groups consisting of six animals in each group. The mice of each group were placed in the beaker (on the hot plate) in order to obtain its response to electrical heat induced pain stimulus. Licking of the paws or jumping out of the beaker was taken as an indicator of the animal’s response to heat-induced pain stimulus. The time for each mouse to lick its paws or jump out of the beaker was taken as reaction time (in second). Before treatment, the reaction time was taken once. The mean of this determination constituted initial reaction time before treatment of each group of mice. Each of the test mice was thereafter treated with either distilled water (DW), Diclofenac sodium (10 mg/kg BW) or ethanol extract of *P. rubra* at the doses of 250 and 500 mg/kg BW orally. Thirty minutes after treatment, the reaction times of each group mice were again evaluated five times individually in one hour interval on this occasion. Percent analgesic score was calculated as,

\[
PAS = \frac{T_a - T_b}{T_a} \times 100
\]

Where, \(T_b\) = Reaction time (in second) before drug administration; \(T_a\) = Reaction time (in second) after drug administration.

2.5.2 Acetic acid-induced writhing method

The analgesic activity of the samples was evaluated using acetic acid induced writhing method in mice following the method of Koster *et al.* with slight modification (Koster *et al.*, 1959; Owoyele *et al.*, 2001; Altun *et al.*, 2009). In this method, acetic acid is administered intraperitoneally to the experimental animals to create pain sensation. The animals were divided into four groups with six mice in each group. Group I animals received distilled water, Group II received Diclofenac sodium at 10 mg/kg while animals of Group III and Group IV were treated with 250 and 500 mg/kg of the ethanol extract of *P. rubra* after an overnight fast. Test samples and vehicle were administered orally 30 minutes prior to intraperitoneal administration of 0.7% v/v acetic acid solution. Animals were kept individually under glass jar for observation. **Each mouse was observed** individually for counting the number of writhing they made in 10 minutes commencing just 5 minutes after the intraperitoneal administration of acetic acid solution. Full writhing was not always accomplished by the animal, because sometimes the animals started to give writhing but they did not complete it. This incomplete writhing was considered as half-writhing. Accordingly, two half-writhings were taken as one full writhing. The number of writhes in each treated group was compared to that of a control group while Diclofenac sodium was used as a reference standard (positive control). The percentage inhibition of writhing was calculated as follows:

\[
\% \text{Inhibition} = (1-V_T/V_C) \times 100
\]

\(V_T\) = number of writhing motions in drug-treated mice

\(V_C\) = number of writhing motions in the control group of mice
2.5.3 Formalin test

The method used was similar to that described previously (Shibata et al., 1989; Viana et al., 1998). The mice were divided into four groups each containing 6 mice and were administered with either distilled water (1ml/kg, i.p.), ethanolic extract of P. rubra (250 and 500 mg/kg, i.p) or Diclofenac sodium (10 mg/kg, s.c). Thirty minutes after this treatment; 50 μl of a freshly prepared 0.6% solution of formalin was injected subcutaneously under the plantar surface of the left hind paw of each mice. The mice were placed individually in an observation chamber and monitored for one hour. The time (in sec) spent in licking and biting responses of the injected paw was taken as an indicator of pain response. Anti-nociceptive effect was determined in two phases. The early phase (phase 1) was recorded during the first 5 minutes, while the late phase (phase 2) was recorded during the last 20-30 minutes after formalin injection.

2.6 Method for the evaluation of anti-inflammatory effect

The anti-inflammatory activity of the ethanol extract was investigated on carrageenan induced inflammation in rat paw following an established method (Winter et al., 1962). Rats were randomly divided into four groups, each consisting of six animals, of which group I was kept as control giving only distilled water. Group II was standard which received Diclofenac sodium (10 mg/kg) as the reference standard for comparison while Group III and Group IV were given the test material at a dose of 250 and 500 mg/kg body weight respectively. Half an hour after the oral administration of the test materials, 1% carrageenan was injected to the right hind paw of each animal. The volume of paw edema was measured at 0, ½, 1, 2, 3, 4 and 6 hours using Plethysmometer (Model 7141, UGO Basile, Italy) after administration of carrageenan. The left hind paw served as a reference non-inflamed paw for comparison.

The average percent increase in paw volume with time was calculated and compared against the control group. Percent inhibition was calculated using the formula-

\[ \% \text{ Inhibition of paw edema} = \frac{V_c - V_t}{V_c} \times 100 \]

Where \( V_c \) and \( V_t \) represent average paw volume of control and treated animal respectively.

3. STATISTICAL ANALYSIS

The data are expressed as the mean ± SEM analyzed by one-way analysis of variance (ANOVA) and Dunnett’s t-test was used as the test of significance. P value <0.05 was considered as the minimum level of significance. All statistical tests were carried out using SPSS statistical software.

4. RESULTS

4.1 Phytochemical analysis

Phytochemical screening of ethanol extract of P. rubra revealed the presence of various bioactive components of which tannin, flavonoid, alkaloid and terpinoid were the most prominent. The result of phytochemical test has been summarized in the Table 1.
Table 1: Phytochemical analysis of the ethanol extract of *Plumeria rubra* bark

4.2 Analgesic activity

4.2.1 Hot plate method

Results of hot plate test are presented in Table 2 for the crude extract of *P. rubra*. The bark extract of the plant significantly increased the reaction time of heat sensation in mice at the doses of 250 and 500 mg/kg BW and the percentage protection is almost equivalent to the respective doses. In the 3rd hour of study, the extract increased the reaction time of heat sensation to 60.81% and 66.52% at the doses of 250 and 500 mg/kg BW respectively while that of the standard drug was 57.40% and the results were found to be highly statistically significant (P<0.001). The extract exhibited a dose dependent increase in latency time when compared with control.

4.2.2 Acetic acid-induced writhing test

Inhibition of licking response in mice due to the administration of the test drugs during acetic acid-induced writhing test is shown in Table 3. The oral administration of both doses of *P. rubra* bark extract significantly (p<0.001) attenuated the acetic acid-induced abdominal writhes in mice in a dose dependent fashion. The percent inhibition of writhing response by the extract was 62.87% and 70.66% at 250 and 500 mg/kg doses respectively while the standard diclofenac sodium (10 mg/kg) showed 50.30% inhibition in comparison with the control.

4.2.3 Formalin-induced writhing test

The effect of the extract of *P. rubra* on formalin induced pain in mice is shown in Table 4. The extract significantly inhibited the licking response in both the early phase (52.84% at 250 mg/kg, p<0.05 and 55.11% at 500 mg/kg, p<0.01) and the late phase (62.24% at 250 mg/kg, p<0.05 and 66.43% at 500 mg/kg, p<0.01) of the formalin test which were comparable to those of the standard drug. Both these inhibition were dose dependent.

4.3 Anti-inflammatory result

The anti-inflammatory effects of the extract and standard drug are presented in Table 5. In control animals, the sub plantar injection of carrageenan produced a local edema that increased progressively to reach a maximal intensity 3 hours after injection. The oral administration of both doses of the ethanolic bark extract of *P. rubra* significantly (p<0.05, p<0.01 and p<0.001) inhibited inflammatory response induced by carrageenan in rats in a dose related manner. The most prominent inhibition of 61.68% at 250 mg/kg and 73.65% at 500 mg/kg were observed at the 4th hour of study after which the inhibitory activity was found to decline. The result was found to be highly statistically significant at 4th hour after administration of the sample drugs (p<0.001).
5. DISCUSSION

Isolation of pure, pharmacologically active constituents from plants remains a lengthy and tiresome process. For this reason, it is crucial to have methods available which eradicate unnecessary separation procedures. Chemical screening is thus performed to allow localization and targeted isolation of new or useful constituents with potential activities. Phytochemical analysis of the ethanolic bark extract of *P. rubra* revealed the presence of tannins, alkaloids, flavonoids, saponins, gums and terpenoids.

Strong occurrence of tannins in extract has been shown to possess potent anti-inflammatory properties (Fawole et al., 2010). There are also reports on the role of tannins in antinociceptive activity (Ramprasath et al., 2006). Flavonoids, also known as nature’s tender drugs, possess abundant biological and pharmacological activities. Analgesic and anti-inflammatory effects have been observed in flavonoids (Rao et al., 1998; Kim et al., 2004; Küpeli and Yesilada, 2007). It is also reported that flavonoids such as rutin, quercetin and luteolin produced significant antinociceptive and anti-inflammatory activities (Pathak et al., 1991; Pelzer et al., 1998). Certain flavonoids possess strong inhibitory activity against a wide range of enzymes such as protein kinase C, protein tyrosine kinases, phospholipase A2, phosphodiesterases and others (Middleton, 1998). Other flavonoids potently restrain prostaglandins, a group of powerful pro-inflammatory signaling molecules (Manthey, 2000). Inhibition of these key enzymes provides the mechanism by which flavonoids inhibit inflammatory processes (Manthey et al., 2001). Alkaloids have been shown to possess anti-inflammatory activity by inhibiting the action of arachidonic acid metabolism via the cyclooxygenase and 5-lipoxygenase pathways (Barik et al., 1992; Chao et al., 2009). Studies have also demonstrated that terpenoids produced significant analgesic and anti-inflammatory activities (Calixto et al., 2000; Neukirch et al., 2005; Moody et al., 2006). They are known to exert their anti-inflammatory effect by inhibiting phospholipase A2, a key enzyme of arachidonic acid metabolism, thereby stopping prostaglandin synthesis (Barar, 2000).

The hot plate test measures the response to a brief, noxious stimulus and thus bears a closer resemblance to clinical pain. The method is considered to be selective for the drugs acting centrally. This test measures the complex response to a non-inflammatory, acute nociceptive input and is one of the models normally used for studying central nociceptive

Table 5: Anti-inflammatory activity of *P. rubra* bark extract using carrageenan-induced rat paw edema method.
activity (Sabina et al., 2009). It is an established fact that any agent that causes a prolongation of the hot plate latency using this test must be acting centrally (Ibironke and Ajiboye, 2007). The ethanolic bark extract of *P. rubra* presented a longer latency time than the control group in the hot plate test in a dose related manner. Therefore, the extract might have a central activity.

Acetic acid induced writhing in mice, attributed to visceral pain, finds much attention to evaluate peripherally active analgesics (Hasan et al., 2010). Pain sensation in acetic acid induced writhing method is elicited by triggering localized inflammatory response resulting in release of free arachidonic acid from tissue phospholipid via cyclooxygenase and prostaglandin biosynthesis (Duarte et al., 1988). In other words, the acetic acid induced writhing has been associated with increased level of PGE2 and PGF2α in peritoneal fluids as well as lipoxygenase products (Deraedt et al., 1980). The increase in prostaglandin levels within the peritoneal cavity then enhances inflammatory pain by increasing capillary permeability (Zakaria et al., 2008). The agent reducing the number of writhing will render analgesic effect preferably by inhibition of prostaglandin synthesis, a peripheral mechanism of pain inhibition (Duarte et al., 1988). Results of the present study show that the plant extract produced significant analgesic effect which might be due to the presence of analgesic principles acting with the prostaglandin pathways.

The formalin test is a widely used model of continuing pain involving peripheral inflammation and central sensitization. The method shows a biphasic response comprising of an early (neurogenic) and a late (inflammatory) phase response and originates mainly from neurogenic inflammation followed by participation of kinins and leukocytes with their pro-inflammatory factors including PGs (Wheeler-Aceto and Cowan, 1991). It is also reported that acute inflammation induced by formalin results from cell damage which provides the production of endogenous mediators (Chen et al., 1995). In the present study, the crude extract produced antinociception against both neurogenic and inflammatory phase of formalin. The fact that the extract at the doses tested produced analgesia in all nociceptive models is indicative that it possesses both central and peripheral antinociceptive effects and the mechanism of action of the extract could, in part, be related to lipoxygenase and/or cyclooxygenase of the arachidonic acid cascade and/or opioid receptors.

Carrageenan-induced inflammation is most commonly used as an experimental model for evaluating the anti-inflammatory potency of compounds or natural products (El-Shenawy et al., 2002). The probable mechanism of action of carrageenan-induced inflammation is biphasic, the first phase is attributed to the release of histamine, serotonin and kinins in the first hour; while the second phase is attributed to the release of prostaglandins and lysosome enzymes in 2 to 4 hours (Brooks and Day, 1991). The second phase is sensitive to most clinically effective anti-inflammatory drugs (Vinegar et al., 1969). The results of present study indicate that the extract significantly inhibited the carrageenan-induced acute inflammation in the 4th hour of study and the finding was comparable to that of the standard diclofenac sodium. So, the anti-inflammatory effect of *P. rubra* extract may be due to its suppressive action on prostaglandin, protease or lysosome synthesis or activity.

6. CONCLUSION

Scientific exploration and standardization of potential crude drugs is an urgent need to revolutionize our drug sector and it is possible as Bangladesh is blessed with many natural forests with huge number of medicinal plants. Based on previous studies and our current investigation, we conclude here that the central and peripheral analgesic and anti-inflammatory effect of the ethanolic bark extract of *P. rubra* may be due to the presence of flavonoids, tannins, alkaloids or terpenoids. These experimental findings lend
pharmacological support to the suggested folkloric uses of the plant in the management and/or control of pain as well as inflammatory conditions. However, further studies are in progress in our laboratory to isolate the active constituents responsible for the observed effect, and to elucidate the possible mechanisms of action responsible for the analgesic and anti-inflammatory activities of the plant extract.

DETAILS OF THE AUTHORS

This is where author information is typed, if desired, such as background, education, main research projects, details of papers, patents, etc. (Details of the main author is expected. But details of the other authors are optional. Selected authors’ profiles will be placed in www.sciencedomain.org).
Dr. Banibrata Das  
Ph.D. (Japan)  
Assistant Professor  
Department of Pharmacy, School of Life Sciences, North South University  
Bashundhara, Dhaka - 1229, Bangladesh.  
Tel: +880-2-8852000, Ext. 1952; Email: banibrata@northsouth.edu

EDUCATION

Ph.D. (2010)  
Department of Frontier Materials, Graduate School of Engineering, Nagoya Institute of Technology, Nagoya, Japan.  
Completion Date: June 2010  
Title of the Thesis: Design and Synthesis of Fluorinated Phthalocyanines.

M. Pharm. (1997)  
Department of Pharmacy, Faculty of Pharmacy  
Held in 1999: University of Dhaka, Dhaka-1000, Bangladesh.  
Title of the Thesis: Bioactivity directed phytochemical investigation of Ludwigia hyssopifolia Linn. (G. Don) Exell.  
Result: First Class

B. Pharm. (1996)  
Department of Pharmacy, Faculty of Pharmacy  
Held in 1997: University of Dhaka, Dhaka-1000, Bangladesh.  
Result: First Class

MM University College, Jessore, Bangladesh  
Result: First Division

Sammilani Institution, Jessore, Bangladesh  
Result: First Division

EMPLOYMENT

July 2010 to Present  
Assistant Professor  
Department of Pharmacy, North South University  
Bashundhara, Dhaka, Bangladesh.

October 2006 to June 2010  
Japanese Government (Monbukagakusho) Scholarship Doctoral Student  
Department of Frontier Materials, Graduate School of Engineering, Nagoya Institute of Technology, Nagoya, Japan.

May 2003 to September 2006  
Visiting Sr. Lecturer  
Department of Pharmacy, University of Development Alternative, Dhanmondi, Dhaka, Bangladesh.
June 2006 to September 2006  Portfolio Manager
Sandoz Division, Novartis (Bangladesh) Limited
Dhanmondi, Dhaka, Bangladesh.

January 2003 to May 2006  Assistant Product Manager
Sanofi-aventis Bangladesh
6/2/A, Segun Bagicha, Dhaka-1000, Bangladesh.

June 2001 to December 2002  Product Officer
Opsonin Pharma Limited
Opsonin Bhaban, 30 New Eskaton Road, Dhaka-1000, Bangladesh.

AWARDS
2010  Vice President Award for Graduate Research, Nagoya Institute of Technology, Nagoya, Japan
2008  Excellent Paper Presentation Award at the 39th Annual Meeting of Union of Chemistry-Related Societies in Chubu Area, Japan
2006  Japanese Government (Monbukagakusho) Doctoral Fellowship
1998  Dean Award for Undergraduate Research
1998  Dean Award for Excellent Result (Hons.) in Pharmacy
1993  Merit Scholarship, Bangladesh Ministry of Education for Outstanding Result in Higher Secondary Certificate (H.S.C.) Examination

MAIN RESEARCH INTERESTS
• Design, syntheses and biological investigation of novel biologically active compounds from existing smaller molecules or lead compounds.
• Pharmacological evaluation of crude plant extracts and compounds isolated from natural sources on experimental animal models and cell lines.
