**ABSTRACT**

Ruminant production that is very popular in Nigeria livestock production faces series of problems, chief among them is the shortage of protein supply in adequate amount for optimum performance of the animals. The forages, which constitute the bulk of the source of feed for these animals, fluctuate in supply with poor nutrient content especially during the dry season of the year. The conventional protein concentrates which boost the protein supply faces intense competition from man. It has become imperative for intensive effort to be made at making the unconventional source of protein available to the farmers. Neem seed cake/kernel cake fits as one of the unconventional protein supply in view of the high level of the protein content and balancing of the amino acids. It is capable of offering a big relief to these protein shortages. The neem seed is readily available in the northern part of Nigeria that is the home to the largest of number of ruminants in the country. However, they are not readily acceptable to the animals due its pungent smell and bitterness caused by the active principles present. This paper reviewed availability of neem seed in Nigeria, antinutritional factors and limitation, methods of processing and debitterizing the cake, nutritional quality, palatability, nutrient digestibility and performance, effect on haematological and biochemical characteristics; and the economics of use of the cake. The paper concluded that neem seed cake/kernel could readily serve as safe source of protein to the ruminants with appropriate treatment to remove active principles.

**Keywords:** Neem kernel cake, Alkali treated neem kernel, haematological, biochemical and Uda Lambs.

**1. INTRODUCTION**

Ruminant production in Nigeria is popular among the rural farmers. They are widely distributed in among rural, urban, and peri-urban areas representing about 63.7% of the total grazing domestic animals in Nigeria (1). It supplies a great proportion of meat consumption. According to (2), the average Nigerian consumes only 3.245g of animal protein per day, out of the 34g recommended by FAO. According to (3), cattle still contribute over 50% of the national meat supply, while other
classes of livestock contribute the remaining 40-45%. Of this, 35% are from small ruminants and about 10% from poultry (3). The level of domestic livestock production still falls short of demand, in 1997 and 1998; demand for beef was 554,000 and 627,000 tonnes, respectively. However, the domestic supplies were 376,000 and 391,000 tonnes for the years 1997 and 1998, respectively (4). The most important factor responsible for the gap in the relationship between the demand and supply of ruminants in Nigeria is the supply of feed both in quantity and quality. The main feed resources for small ruminants are natural pastures consisting of legumes and browse species (5). These pastures depend on rainfall which fluctuates especially in the northern part of the country where the largest percentage of the animals are raised.

According to (6), the scarcity of energy and protein feedstuffs during dry season is a major setback to ruminant livestock production in the tropics. During this period, the available forages are dry, protein content of which is very low and there is marked decrease in voluntary intake and digestibility by the animal (7; 8). The nutritional problems of ruminants have been increased by competition between man and the animals for the scarce grains and the protein concentrates feed making it difficult to meet up with nutritional requirements of the animals at affordable cost.

Some of the factors which contributed to the increasing cost of feed are under-production of various ingredients used in feed formulation, high inflation rates and competition in consumption of these ingredients by other animal species including man. The increase in human population further worsens the situation because of pressure placed on the available land for grazing, competition for grains and other crops that are consumed by man but do not have a commensurate increase with that of human population and inappropriate employment of technology for improved production.

The commonest protein supplement for livestock feed in Nigeria in periods of low yield and availability of poor quality herbage are groundnut cake (GNC) and cotton seed cake (CSC). The prices of GNC and CSC products have been rising thereby increasing the cost of production. Researchers therefore considered the use of alternative source of feed ingredients in order to reduce the cost of production. One of the promising materials under consideration is the neem kernel cake. However, despite its availability and the derivable benefits from the use of the cake, its use is still beleaguered by series of problems.
The main objective of this study is to create awareness on the potentials of the use of neem seed cake in Nigeria. The study will further dwell on the nutritional and antinutritional components; and the different methods of debitterizing the cake.

2. METHODOLOGY

Secondary materials obtained from published journals and reports were for review of this study.

3. DISCUSSION

3.1 Neem Seed Availability

Neem tree is planted in many states in Nigeria (9). According to (10), about 3,500 hectares of land is under cultivation in Kebbi, Sokoto and Zamfara states, with a density of about 1,200 trees per hectare. In Nigeria, neem form about 90% of forestry established in 12 states within the savanna zone under the aorestation programme (11). The neem tree does well in well drained deep soil, sandy loams with ground water level at 3.05 metre depth or more. The Neem tree (Azadirachta indica) is an evergreen of the tropics and subtropics: It is native to India but widely planted and naturalized throughout Asia, Africa, Australia, the Caribbean and several Central American countries (12). It may grow up to 15m tall under ideal conditions and is reported to live up to 200 years (12). The tree has the ability to withstand frost due to a very suberised back layer and can easily survive desert conditions of temperature above 50°C and takes about five years to produce the first fruit crop but can produce a good yield in the third year (13). The tree has the advantage of growing on marginal lands (14). Neem tree can perform well in dry soils that are poor in nutrients (130mm) (15). Neem tree flowers between February and May with profuse clusters of small white flowers. The fruits are drupes, turning golden yellow on maturity, which occurs during June, to August in India. The tree begins bearing fruit after 3 to 5 years and produces about 50kg fruits annually when mature in India. The fruits are about 1.5cm long (12). According to (13), the seeds are about 2cm long and 1.5cm diameter, kernel of about 1.5cm length containing about 30 to 40 percent oil and 5 to 6 years old tree can yield 20kg kernels. However, Radwanski (15) reported that fruit yield is extremely variable ranging from 10 to 50kg per tree with an average of 20kg. The yield of 20.5kg fresh fruit for a fully grown neem tree was reported by NARICT (9) in Nigeria while (16) reported an average yield of 17.71kg in Sokoto and
its environ. The large number of the neem trees and its yield in the northern part of Nigeria is an advantage for its use.

3.2 Anti-nutritional Factors and Limitation of Neem Seed Cake as Feed Ingredient

The possibility of using NSC in livestock ration was explored by Christopher (17) using the feeding practice of local farmers in Southern India. However, NSC pungent odour and the bitter taste caused by the active principles isolated from different parts of the plant namely azadirachtin, meiacin, gedunin, salanin, nimbin, valassin and many other derivatives of these principles constitute the hindrances to its use. Paul et al. (18) reported that despite the high CP content, its incorporation in animal diets was discouraged due to their adverse effect on production traits because of the presence of bitter and toxic triterpenoids mainly nimbin, nimbidin, azadrachtin and salanin. The triterpenoids: azadirone, nimbin and salanin have impacted the pungent smell and bitter taste of this cake (19).

Biologically active principles isolated from different parts of the plant include: azadirachtin, meiacin, gedunin, salanin, nimbin, valassin and many other derivatives of these principles. (20) reported the presence of toxic triterpenoids, azadirone, nimbin and salanin in neem seed cake. Meiacine forms the bitter principles of the neem oil; the seed also contain tignic acid (5-methyl-2-butanic acid) responsible for the distinctive odour of the oil (21, 22,23, 24). Neem seed cake is very unpalatable due to the presence of salanolide meiacin which has been found to be one of the active principles of neem seed oil (25). These compounds are natural products called triterpenoids or more specifically, linonoids and they are concentrated in the seed despite their presence in other parts of neem tree.

Neem seed is bitter and pungent in odour. The bitter taste and pungent odour resulting in poor palatability discourage animals from eating it. These compounds influence the palatability of the NSC. NSC has been found to be unpalatable in calves (26), cross-breed bulls(27) and sheep (28). The active principles are slightly hydrophilic but freely lipophilic and highly soluble in organic solvents like hydrocarbon, alcohols, ketones and esters (22,21). (29) reported that poor palatability was accompanied by either poor weight gain or loss of body weight along with lowered nutrient digestibility in crossbred calves fed concentrate mixture containing NSC that contributed 12.5, 25, or 50% of DCP requirement. The author suggested that NSC was unsuitable for animal feeding even for maintenance. (30) observed a gradual decline in growth rate of rams with higher levels of NSC in concentrate ration. This then makes the processing of the cake
before being fed to animals very important. The processing of the neem seed into palatable seed cake poses a challenge to its use as animal feed.

3.3 Methods of Processing and Debitterizing of Neem Seed Cake

Single seeded mature neem fruit contains 23.8% skin, 47.5% pulp, 18.6% shell and 10.1% kernel (31). The decortications of depulped seed yields about 26% kernel, which gives 45 to 50% oil leaving the rest as neem kernel cake (NKC). Neem seed cake could not earn favour as a good livestock feed due to its pungent smell and bitter taste imparted by the presence of toxic triterpenoids: azadirone, nimbin and Salanin (20). The impact of the effect of the toxic substances in NSC has over time place so much emphasis on the processing of the seed for these toxic substances to be removed. The removal of the anti-nutritional factors of neem seed can be done through different methods of processing.

According to (20), before oil extraction, neem fruits should be soaked in water for 3-4 days and depulped using depulper machine. The seeds decorticated using a winnowing machine and then crushed after further drying for 3 days. The ripe fruits were dried by spreading them in the sun for fifteen days and ground to produce the neem fruit cake. The ripe fruits were dried, soaked in water for three days and then depulped. The depulped seeds were washed and sun dried for a period of ten days. The dry seeds were decorticated, further dried for five days, crushed and the oil removed manually to produce the neem kernel cake. (16) prepared by spreading the ripe fruits were dried by spreading them in the sun for fifteen days and ground to produce the neem fruit cake. The ripe fruits were dried, soaked in water for three days and then depulped. The depulped seeds were washed and sun dried for a period of ten days. The dry seeds were decorticated, further dried for five days, crushed and the oil removed manually to produce the neem kernel cake while (32) reported that collected seeds were sun dried to constant weight. The dried seeds were soaked in water in an open basin for 72 h. The seed were poured into a jute bag to drain the water and later sun-dried to constant weight. Then, the water soaked and untreated seeds were taken to the mill separately for oil extraction. Cake obtained from the oil-extraction was then ground in a hammer mill to pass through 2 mm sieve.

There are various methods of removing the oil from the neem seed cake. For the expeller neem seed cake, the crushed kernel will be steamed and the oil is pressed out using expeller machine. The hydraulic press neem seed cake processing is devoid of heat. The milled kernel was cold-pressed using the hydraulic press machine until the oil content of the residue (cake) is minimal. To reduce the oil content of the cake, it is further defatted using hexane. Attempts have been made at removing the bitter principles or debitterizing the cake for improved palatability. (33) and
(34) adopted the solvent extraction method in which the oil from the crushed neem kernel or cake is extracted using organic solvent of high polarity mixed with water and filtered. Alcohol treatment (35), alkali (0.8% NaOH, wt/wt), boiling (1:2.5 wt/vol) of cake followed by water washing and draining off after washing (36). Of the several methods tried to detoxify NKC, for example water washing (37), hexane extraction (38), alkali treatment of neem kernel cake (38) and water washing which was found to be most effective despite the loss of 22% dry matter (39). However, to avoid this dry matter loss from water washing, alkali treated (20g NaOH/kg cake, wt/wt) NKC was tried and found to be palatable to adult cattle and buffalo (40), proved promising in the feeding of buffalo calves (41) and Uda lambs and rams (16). (42) also used the simple method for debitterization through alkali soaking or urea ammoniation without water washing because there is loss of nutrient in washing. Such alkali (2.5%, wt/wt NaOH) soaked and urea (3.5%, wt/wt) ammoniated NKC at 30 parts of inclusion in the concentrate mixture of buffalo calves for 150 days feeding revealed comparable feed intake and nutrient utilization.

3.4 Nutrient Digestibility and Performance

Feeding neem seed cake/kernel without treatment has been shown to have negative effect on nutrient digestibility and performance of ruminants. (43) fed 27% neem seed cake as a replacement to groundnut cake with consequent poor growth in cattle. (44) reported poor palatability accompanied by either depressed weight gain or loss of body weight along with lowered nutrient digestibility in crossbred calves fed concentrate mixture containing NSC to contribute 12.5, 25.0 and 50.0% of digestible crude protein requirement suggesting that the NSC as such was unsuitable for animal feeding even for maintenance. (45) reported lowered rumen protozoan count along with reduced enzyme activity in calves fed NSC.

However, there were reports of improvement in the digestibility and performance of ruminants when fed treated neem seed cake/ neem kernel cake. (39) attempted water washing of NKC after overnight washing in NaOH (0.8%, wt/wt) followed by repeated draining off with two or three times water washing. Such water washed NKC (WWNKC) when incorporated after sun drying at 45% level in the concentrate mixture for bull calves for 273 days resulted in significantly lower growth rate and comparable DM intake, nutrient digestibility, balance of Ca, P, N and TDN intake with the control. (36) observed significantly lower DM digestibility, but higher N-balance and faster growth of buffalo calves fed 40% WWNKC than in those on control diet. (46) reported no significant variations in milk yield, milk fat content, and sensory evaluation of milk, dry matter intake and digestibility when water washed neem kernel cake was incorporated at 40% level in the concentrate diet of dairy cow for 300 days. The reports of (47) showed that treatment of neem kernel meal with alkali improved the growth performance, and that of (48) showed improvement in growth when goats were fed urea ammoniated neem kernel cake. (49) reported comparable performance between the growth performance of Uda lambs fed alkali treated neem kernel cake.
3.5 Nutritional Quality of Neem Seed Cake

Neem (Azadirachta indica) seed cake (NSC), a by-product of neem oil industry, is a non-conventional feed ingredient with great potential for livestock feeding (50, 33). Neem seed cake has been noted as a rich protein source with 34% - 38% CP (20) and; 33.20% and 32.90% for ATNKC and NKC respectively (16). Deoiled neem seed cake is rich in essential amino acids, crude protein, fibre contents, sulphur and nitrogen (23). Neem seed cake balanced in minerals as shown in Table 1. It is balanced in Ca, P but exceptionally high kernel Fe.

FFNSM: Full fat neem seed meal

The gross protein value of variously processed neem seed meal (NSM) ranged from 55 to 59% (51). The undecorticated NSC contained 6.5 to 11.6% digestible crude protein (27). (20) reported crude protein percentage of 23.19%, 22.69%, 23.06% and 22.5% for raw neem seed meal, hydraulic press neem seed cake, solvent extracted Neem seed cake and expeller neem seed cake respectively. The protein quality of neem kernel cake is comparable to that of peanut meal (PNM) (52). Neem cake consists of all essential and non-essential amino acids including sulphur containing ones, but with fewer amounts of histidine, lysine and tyrosine (52).

Chemical composition of neem seed cake is shown in Table 2 and varied considerably depending on the method of processing. The crude protein (CP) varied from 12.35% in neem seed cake (NSC) to 40.91% in urea treated neem kernel cake (UANKC). The crude fibre was highest in full fat neem seed meal of 40.50% as reported by (53). (38) reported the lowest value in neem kernel
cake of 11.40%. The ether extract (EE) varied from 0.38% in deoiled neem seed cake (54) to 27% in full fat neem seed meal (52). The nitrogen free extract was the lowest in full fat neem seed meal (18) with 14% and highest in neem seed cake (26) with 52.52%. UANKC (42) seemed to be the best because of high crude protein of 40.91% and relatively low crude fibre of 11.43%.

Alkali treated neem kernel cake consisted of 33.76% crude protein and 13.77% crude fibre (41). The authors also reported that alkali treated neem kernel cake can be a wholesome substitute for peanut meal in terms of performance. Water washing was found to be an effective method of detoxifying neem seed cake but there was loss of dry matter of about 22% (39). In addition, some enzyme stimulating factors are also washed out as indicated by Agrawal et al. (55). Alkali treatment was adopted to avoid the water loss and was found to be palatable to adult cattle and buffalo (41) and buffalo calves (40).

Palatability of Neem Seed Cake/Kernel

Neem seed cake is unpalatable due to the presence of salanalide meliacin which has been found to be one of the active principles of neem seed oil (25). The seed contains Tigonc acid (5-methyl-2-butanic acid), which is believed to be responsible for the distinctive odour of neem oil. These compounds are natural products called triterpenoids or more specifically linonoids and they are concentrated in the seed despite their presence in other parts of neem tree. The compounds influence palatability of the NSC. NSC has been found to be unpalatable in calves (26), cross-breed bulls, (27) and sheep (28). However, the palatability of the NSC can be improved with appropriate treatment to remove the active principles. According to (59), NSC palatability improved when NSC was fed to sheep along with barley, molasses and peanut meal but consumption of concentrate mixture was reduced from 79 to 39% when NSC levels increased from 59% to 90% respectively. Yearling sheep could completely consume concentrate mixture comprising 75 parts NSC and 25-part maize (28). However, the consumption was reduced to one third when NSC was fed alone. Buffalo calves though continued to relish even after enhancing NSC from 5 to 15 parts when fed along with 7 and 20 parts of molasses and peanut meal respectively, the consumption was reduced to half on withdrawal of molasses (60). Depression of 60% feed intake could be corrected by curtailing NSC to provide digestible crude protein requirement from 25 to 12.5% in the ration of buffalo calves (26). (49) reported improved palatability when neem kernel cake was treated with an alkali (NaOH).

### 3.6 Effect on Haematological and Biochemical Characteristics

The use of treated neem seed cake/neem kernel cake in the feed of ruminants has been proven to be safe for their consumption. (16) reported that feeding of alkali treated neem kernel cake to lambs up to 20% level has no significant effect on the haematological and biochemical
characteristics. (60) reported that neem bitterness and toxicity can be inactivated by alkali
treatment. This was also supported by (42) in his report that alkali treated neem kernel cake can
convert neem kernel cake to a wholesome vegetable protein supplement for growing buffalo
calves. According to (61), inclusion of water washed neem kernel cake in the concentrate mixture
of male kids at 15 and 25 parts for 180 days of feeding led to comparable intake and utilization of
nutrients, besides normal balance of nitrogen, urinary creatine, blood haemoglobin, cholesterol
and activities of Glutamate oxalo acetate transaminase (GOT), Glutamate pyruvate transaminase
(GPT) and alkaline phosphates with significantly lowered blood glucose, urea and total protein.

(16) reported that the Serum glutamate oxalo acetate transaminase (SGOT) and Serum glutamate
pyruvate transaminase (SGPT) values in the control and test diets Uda lambs fed alkali neem
treated kernel cake were comparable. He also showed that the Bilirubin total, Bilirubin Conjugate
and Bilirubin unconjugate values in the study were normal and conformed to the report of (62)
and (63). These values were within the range of 14-123u/l for SGOT and 15-44u/l for SGPT
reported by (63). These indicate that inclusion of ATNKC is not toxic to the liver. (64) reported
that SGPT and SGOT were excellent markers of liver damage caused by exposure to toxic
substances. (65) reported that incorporation of NSC up to 20% did not alter GOT and GPT
activities in the blood. The urea nitrogen level of lambs fed alkali treated neem kernel cake and
control in the report of (16) were not significantly different from each other and were all within the
normal range reported for sheep by (63) and (62). The authors also showed that the Sodium and
Potassium level obtained the blood of Uda lambs fed alkali treated neem kernel cake were
normal and within the range of 142-160mmol/l for Sodium and 4.3-6.3mmol/l for potassium
reported by (63) and that of (66) of 153mmol/l and 4.7mmol/l for Sodium and Potassium
respectively. This indicate that ATNKC inclusion up to 20% level did not interfere with the renal
functions of the animals.

3.7 Economics of use

Neem seed cake has proven to be economical in the feed of ruminants. (67) in the study
conducted with Uda lambs and rams as shown in tables 3 and 4 showed that the use of treated
neem seed cake in the feed of ruminants as shown compares favourably in cost of feed gain, cost
of feed consumed and cost of feed per live weight gain.

(50) also reported 20% lower cost per weight gain when he replaced deoiled peanut with urea ammoniated neem kernel meal in goats. (20) reported that hydraulic pressed neem seed cake had the least cost per kg liveweight gain among dietary treatments including the control in rabbits. (68) reported that the cost of feed per kg liveweight gain was less for diets with inclusion of detoxified neem seed cake than with the conventional feed in Nellore sheep.

4.0 CONCLUSION

Neem seed is readily available in Nigeria especially in the northern part. It can easily be converted to neem seed cake/kernel cake. The active principles present in the seed have resulted in bitterness and pungent smell which have impacted negatively on the palatability and the consumption. However, with appropriate method of preparing the cake and removing the active principles, its palatability and the consumption has been found to improve resulting in comparable performance in animals fed treated neem seed cake/ kernel cake and the control diets without any adverse effect on the haematological and biochemical parameters. Treated
neem seed cake/kernel cake can readily fit in as replacement for the convectional protein sources.
