The clinical significance as below should not be in the abstract section. It should be in the discussion section. Otherwise the 2nd revised manuscript could be acceptable.

**Clinical Significance:** Measurements of respiratory resistance and vocal cord images during or immediately following exercise, which both require exclusive access to the mouth, cannot be made simultaneously, but this study demonstrates that both measurements can be made sequentially without loss of accuracy, as long as the two measurements are made within 30 seconds before and after the cessation of exercise. Measurements made with the APD, or other respiratory resistance measuring device, just before exercise ceases can be directly compared with laryngeoscope images made soon after exercise cessation.
