ABSTRACT

Aims: The study was designed to investigate the testiculoprotective effects of ethanolic roots extract of Pseudocedrela kotschyi on alloxan-induced testicular damage in diabetic rats.

Study design: Experimental diabetes using animal models.

Place and Duration of Study: Department of Anatomy, College of Medicine, Lagos State University, Ikeja, Lagos, Nigeria, between January, 2013 and May, 2013.

Methodology: Twenty male rats were divided into four groups: Group I consisted of non-diabetic rats that received only the vehicle; group II-IV was injected with a single dose of alloxan (ALX) of 150 mg kg⁻¹ intraperitoneally; groups III and IV were given ethanolic roots extract of Pseudocedrela kotschyi orally, 3 days after the ALX administration, at daily doses of 250 and 500 mg kg⁻¹ respectively for a period of 30 days. After 4 weeks of treatments, all the rats were sacrificed.

Results: Administration of 150 mg kg⁻¹ of alloxan to male rats induced diabetes and significantly reduced the body and testicular weights, testosterone levels, sperm count and motility, significantly increased the glucose level and decreased the levels of antioxidant enzymatic and non-enzymatic markers such as glutathione (GSH), catalase (CAT), superoxide dismutase (SOD), glutathione peroxidase (GPx) and while the level of malondialdehyde (MDA) was significantly increased. By contrast, rats given the ethanolic roots extract of Pseudocedrela kotschyi had significantly increased (p<0.05) in body weight gain, whereas the glucose levels significantly improved (p<0.05) in treated diabetic male rats. In addition, this extract improved the reproductive system of the diabetic male rats by significantly increasing the testis and epididymis weights, testosterone levels, sperm count and motility, reduced testicular GSH, CAT, SOD, GPx and significantly decreasing MDA. The extract had no deleterious potentials and testicular cytoprotection damaged by ALX.
Conclusion: We concluded that the adverse effects of ALX-diabetes on reproductive system of male rats can be reversed by treatment with the extract of *Pseudocedrela kotschyi* which exhibits antihyperglycemic and fertility activities.

Keywords: [Antihyperglycemia; antioxidants; spermatogenic activities; alloxan; rats; *Pseudocedrela kotschyi*]

1. INTRODUCTION

Diabetes mellitus (DM) is a metabolic disorder with developing pathological complications [1]. DM is mainly due to relatively low level of insulin production or an inability of the body to use insulin properly which, in turn, leads to hyperglycemia [2].

Hyperglycemia has been recently implicated in induction of oxidative stress which, in turn, leads to initiation and development of diabetic complications. Diabetic complications are many and include physical disability, kidney failure, visual impairment, cardiovascular disease and sexual dysfunction [3]. The direct effects of insulin lack depletion on male reproductive system of male rats have been reported by several investigators [4]. It has been reported that the administration of high doses of alloxan (ALX) administered to male rats leads to a decrease in Leydig cell function, testosterone production, sperm output and fertility [5].

Many plants have been shown to possess antidiabetic and hypoglycemic properties by lowering the blood glucose levels and reducing the various complications associated with diabetes. For example, the antifertility activities of extracts from *Carica papaya*, *Quassia amara*, *Moringa oleifera*, *Azadirachta indica* and *Zingiber officinale* had been documented anti-diabetic properties had been reported [6-10].

*Pseudocedrela kotschyi* (PK) is a member of the family Meliaceae. The plant is widespread in savannah woodland [11-12]. It is a tree of up to 20 m high with a wide crown and fragrant white flowers [12]. It is commonly found in West and Tropical Africa and in abundance particularly in North Central Nigeria. It is commonly known as Emi gbegi among Yoruba’s and Tuna among Hausa’s. In Togo, the bark is used as a febrifuge and for the treatment of gastrointestinal diseases and rheumatism [11]. The plant has also been reported to be used traditionally in the treatment of dysentery [12]. The analgesic, anti-inflammatory activities of plant have also been reported [13], antiepileptic [14], and dental cleaning [15-16]. This plant has demonstrated a wide range of biological effects such as antimalarial [17], anticonvulsant [18], antibacterial [19], antimicrobial [20], antipyretic [21] and antidiabetic activities [22-23].

However, despite of widespread use of *Pseudocedrela kotschyi* as in folklore medicine to manage DM and other ailments, its protective effects on the reproductive system has not been established elaborated. Alloxan (it is important to note that administration of ALX) induced diabetes in rats provides a good model to study reproductive defect, because as ALX induced diabetic rats exhibit a number of defects in reproductive organs that resemble those seen in diabetic humans. Therefore, the present study was designed to evaluate the testiculoprotective effects of ethanolic roots extract of *Pseudocedrela kotschyi* on alloxan induced testicular damage in reproductive structures and functions of male alloxan-induced rats.

Comment [O5]: lack of insulin
2. MATERIAL AND METHODS

2.1 COLLECTION OF THE PLANT MATERIAL

*Pseudocedrela kotschyi* (PK) roots were collected from cultivated farmland at Kulende, Ilorin, Kwara State, Nigeria. The plant was identified and authenticated at Forestry Research Institute of Nigeria (FRIN), where voucher specimen has been deposited in the herbarium (FHI 108280).

2.1.1 Preparation of the plant extract

The roots of the plant were shade-dried at room temperature for 7 days and then powdered using mortar and pestle. 550 g of the root powder was soaked in ..... ml of 96% aqueous alcohol in three 3 cycles using soxhlet extractor. The crude extract was filtered through filter paper (Whatman No 4), and t The filtrate was concentrated and dried in a rotary vacuum evaporator under reduced pressure in vacuole at 30°C to obtain 97.2 g dry residue to yield an (14.9% vol.) viscous brownish-coloured extract which was stored in an air tight bottle kept in a refrigerator at 4°C till used [24].

2.2 EXPERIMENTAL ANIMALS

Twenty healthy male albino rats weighing between 160-180 g were obtained from the Laboratory Animal Center of College of Medicine, Lagos State University, Ikeja, Lagos, Nigeria. The rats were housed in clean cages with the filter tops under controlled conditions of 12 h light/12 h dark cycle, 50% humidity at 26±2°C and kept in a well-ventilated room and allowed to acclimatize to the laboratory condition for two weeks before being used. They were maintained on a standard animal pellet (CHI Feeds Plc., Nigeria) and had free access to water ad libitum. These experiments complied with the guidelines of our animal ethics committee which was established in accordance with the internationally accepted principles for laboratory animal use and care.

2.3 ACUTE TOXICITY STUDIES

The acute toxicity of ethanolic roots extract of *Pseudocedrela kotschyi* were determined by using thirty-five (35) male Swiss albino mice (20-22.5 g) which were maintained under the standard conditions. The animals were randomly distributed into a control group and six treated groups, containing five animals per group. After depriving them food with 14 h prior to the experiment with access to water only, the control group was administered with single dose of ethanolic roots extract of *Pseudocedrela kotschyi* with at a dose of 0.3ml of 2% acacia solution orally while each treated group was administered with single dose of ethanolic roots extract of *Pseudocedrela kotschyi* orally with at a doses of 1.0, 2.5, 5.0, 10, 15 and 20.0g/kg body weight respectively of 2% acacia solution. They were closely observed in the first 4 hours and then hourly for the next 12 hours followed by hourly intervals for the next 56 hours and continued for the next 2weeks after the drug administration to observe any death or changes in behaviour, economical, neurological profiles and other physiological activities [25-26].
2.4 EXPERIMENTAL DESIGN

To induce diabetes, rats were first anesthetized with inhalation of gaseous nitrous. Alloxan® (Sigma, St, Louis, MO, USA) was purchased from representative of Sigma Company in Nigeria and was prepared in fresh normal saline. Diabetes was induced by intraperitoneal (ip) injection of alloxan monohydrate (150 mg/kg bwt) in a volume of 3 mL [27]. After 72 h, blood was withdrawn for blood glucose estimation monitored with a glucometer (ACCU-CHEK, Roche Diagnostics). The animals with blood glucose level ≥ 250 mg/dl were considered diabetic and included in the experiment [28].

The diabetic animals were randomly distributed into three groups of five animals each while the last group, the positive control, had five normal rats.

Treatments were as follows:
Group I: Normal rats received only vehicles (0.5 mL/kg body weight), and served as control.
Group II: Alloxan diabetic rats that received only vehicles (0.5 mL/kg body weight).
Group III: Alloxan diabetic rats treated with *Pseudocedrela kotschyi* at a dose of 250 mg/kg bwt
Group IV: Alloxan diabetic rats treated *Pseudocedrela kotschyi* with at a dose of 500 mg/kg bwt.

Treatments were administrated every day by intragastric gavage. Rats were maintained in these treatment regimens for four weeks with free access to food and water ad libitum. Every week measurements of body weight were recorded for 4 weeks.

2.5 SAMPLE COLLECTION

Samples were collected every week from each animal for blood glucose analysis and the remaining blood sample was put into sterile tubes and allowed to clot for 30 min and centrifuged at 4000 rpm for 10 min using a bench top centrifuge. Serum was collected and kept at -20°C for hormone determination. At the end of the experimental period, each rat was weighed and starved for 24 h. Then, blood samples were collected from each animal by cardiac puncture and rats were sacrificed under light ether anaesthesia. Epididymis and testes were carefully dissected out and rinsed in cold saline solution, weighed and processed immediately as described below.

After one month of treatment, the animals were sacrificed by decapitation. The trunk blood was collected and 2 ml of blood were distributed into tubes containing an anticoagulant agent, followed by centrifugation at 3000 rpm for determination of plasma glucose level. The remaining blood was placed in a dry tube, centrifuged and the serum was aliquoted into 1.5 ml vials, and frozen at -20°C for determination of testosterone level. Testis and epididymis were excised immediately, washed with ice-cold physiologic saline solution (0.9%, w/v), blotted and weighed. About 1 g of each organ was cut into small pieces homogenized with an Ultra Turrax homogenizer in 2 ml ice-cold appropriate buffer (pH 7.4) and centrifuged at 9000 rpm for 15 min at 4°C. Supernatants were collected, aliquoted and stored at -60°C until use for enzyme assays.

2.6 GLUCOSE AND TESTOSTERONE DETERMINATION
Glucose was measured by the glucose oxidase method using a commercially available kit (ACCU-CHEK, Roche Diagnostics). All serum samples were assayed for testosterone using tube-based enzyme immunoassay methodology (EIA) and the absorbency was read at 450 nm as described by Raji et al. [29]. The EIA kits were obtained from DiaSys (Germany).

2.7 EVALUATION OF EPIDIDYMAL, SPERM COUNT AND MOTILITY

Epididymal contents were obtained after cutting the tail of epididymis, squeezing it gently on clean slide and the sperm progressive motility and cell count were determined according to the method described by Yokoi et al. [30]. Briefly, the cauda epididymis was minced with anatomical scissors in 2 ml of Earles buffer placed in a rocker for 10 min at 37°C. After dilution, the number of homogenization-resistant spermatozoon was counted in a haemocytometer and about 25 fields of view were examined under a light microscope at 40× magnification.

2.8 EVALUATION OF TESTICULAR ENZYMATIC ANTIOXIDANTS

2.8.1 Assay of catalase (CAT) activity

Catalase activity was evaluated according to the method described by Aebi [31]. Activity of catalase was expressed as units mg⁻¹ protein.

2.8.2 Assay of superoxide dismutase (SOD) activity

Superoxide dismutase activity was evaluated according to the method described by Winterbourn et al. [32]. It was expressed as u mg⁻¹ protein.

2.8.3 Assay of glutathione peroxidase (GPx) activity

Glutathione peroxidase activity was determined by the method described by Rotruck et al. [33]. The absorbance of the product was read at 430 nm and it was expressed as nmol-protein.

2.9 EVALUATION OF TESTICULAR NON-ENZYMATIC ANTIOXIDANTS

2.9.1 Assay of testicular reduced glutathione (GSH) activity

Reduced glutathione (GSH) was measured according to the method described by Ellman [34]. The absorbance was read at 412nm, it was expressed as nmol-1 protein.

2.9.2 Assay of lipid peroxidation (Malondialdehyde)

Lipid peroxidation in the testicular tissue was measured colorimetrically by thiobarbituric acid reactive substance (TBARS) method described by Buege and Aust [35]. Concentration was estimated using the molar absorptive of malondialdehyde which is 1.56×10⁵ M⁻¹ cm⁻¹ and it was expressed as nmol mg⁻¹ protein.

2.10 HISTOLOGICAL ANALYSIS
This was done as described by Kusemiju et al. [36]. Briefly, after 48 h the organs were removed from Bouin’s fluid and fixed in fresh Bouin’s fluid for another 72 h. Each testis was sliced into slabs of about 0.5 cm thick and dehydrated in varying degree of alcohol (70%, 90%). From 90% alcohol to 3 changes of absolute alcohol for 1 hour each, then into chloroform for about 10 h and later transferred into fresh chloroform for about 30 min. The tissues were placed in 3 changes of molten paraffin wax for 30 min each in an oven at 57 °C. They were placed vertically in molten paraffin wax inside a plastic mould and left overnight to cool and solidify. They were later trimmed and mounted on wooden blocks. Serial sections were cut using a rotary microtome at 5 µm thickness. Sections were floated in a water bath and picked by albuminized slides and dried on the hot plate at 57 °C. To stain, the slides were de-waxed in staining racks and placed in staining wells containing xylene and rehydrated in varying degree of alcohol (absolute, 90%, and 70%) and then to water for 5 min after which they were stained with heamatoxylin for 3 min. Excess heamatoxylin was washed off with water and differentiated with 1% acid alcohol. Sections were rinsed under running tap water and then left for 5 min for blueing. Sections were counterstained with 1% eosin and washed off with water. They were dehydrated with 70%, 90% and absolute alcohol and cleared in xylene to remove all traces of water. A drop of mountant was placed on the surface of the slide and covered with a 22 by 22 cm cover slip. Light microscopy was used for the evaluations and the photomicrographs were taken.

2.11 STATISTICAL ANALYSIS

Data are presented as means ± SD. Student’s t-test analysis was applied to test the significance of differences between the results of the treated, untreated and control groups. The difference was considered significant at the conventional level of significance (p < 0.05).

3. RESULTS AND DISCUSSION

3.1 ACUTE TOXICITY

The acute toxicity study result (Table I), showed that four out of the five animals that received 20.0 g/kg bwt of the extract died within 4 h (80 % death) while the animals that received 2.5 g/kg body weight survived beyond 24 h. The LD$_{50}$ of the drug was therefore calculated to be 15 g/kg bwt. The LD$_{50}$ of the extract was determined by plotting a graph of probit on the Y-axis against the log dose on the X-axis.

#### 3.2 EFFECT ON BODY WEIGHT OF MALE RATS:

To determine the effect of treatment of *Pseudocedrela kotschyi* extract on body weight in the ALX-treated rats, the animals (Table II) showed decrease in appetite and weight depreciation after alloxan induction. All rats were monitored for gain in body weight. The control group (I) gained weight over the four weeks of experimental period, with the mean body weight increasing by 29 g after 4 weeks (Table II). In contrast, the untreated diabetic group (II) lost an average of -25.6 g after 4 weeks (p<0.05). Treatment with *Pseudocedrela kotschyi* resulted in significant weight gain to levels approaching the control group (Groups III and IV, versus Group I). In the untreated group, progressive weight decrease occurred while in the extract treated groups, there was weight appreciation after few days of treatment as well as showed increase in appetite.

3.3 EFFECT ON SERUM GLUCOSE CONCENTRATION:

An increase in serum glucose concentration (mg dL\(^{-1}\)) was recorded in untreated diabetic group, relative to the control group (Table III). After four weeks, the serum glucose concentration in untreated diabetic group increased to 362.2 mg dL\(^{-1}\). In treated diabetic rats (Groups III/IV), the serum glucose concentration decreased to 254.2 and 242.7 mg dL\(^{-1}\), respectively, after four weeks, which was significantly less than that in the untreated diabetic group (p<0.05).

3.4 EFFECT ON SERUM LEVEL OF TESTOSTERONE:

The diabetic rats showed a decrease in serum testosterone levels compared to level of the control rats (Table IV). Treatment of the diabetic rats with _Pseudocedrela kotschyi_ (Groups III/IV) caused a significant increase in the levels of testosterone in a dose-dependent manner (p<0.05).

3.5 EFFECT ON SEX ORGAN WEIGHTS, SPERM COUNT AND MOTILITY OF MALE RATS:

Table IV shows that the weight of testes and epididymis of diabetic untreated group were significantly lowered at the fourth week as compared with those of the control group (p<0.05). Treatment of the diabetic male rats with _Pseudocedrela kotschyi_ (Groups III/IV) caused a significant increase in testis and epididymis weights (p<0.05). On other hand, sperm count and motility of untreated diabetic group were also lowered, as compared with those of the control group. This reduction was statistically significant (p<0.05). Furthermore, administration of ethanolic roots extract of _Pseudocedrela kotschyi_ for 4 weeks showed a significant improvement in the sperm count and motility of treated diabetic groups.
(Groups III/IV) in a dose-dependent manner (p<0.05). However, the sperm count and motility of the treated diabetic groups (III and IV) were still lower than those of control group I.

3.6 EFFECT ON TESTICULAR ENZYMATIC AND NON-ENZYMATIC ANTIOXIDANTS

Diabetic rats showed significant lowering (p<0.05) in superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx) compared to the control animals (p<0.05). Diabetic rats treated with the *Pseudocedrela kotschyi* *P. kotschyi* showed significant higher (p<0.05) in testicular SOD, CAT and GPx activities compared to diabetic rats without treatment (p<0.05). Along the same line for the testicular content of glutathione (GSH) and malondialdehyde (MDA), GSH level in diabetic rats was significantly lower (p<0.05) compared to normal rats (p<0.05). However the diabetic rats treated with the *P. kotschyi* showed significantly increase in the testicular content of GSH compared to normal rats (p<0.05), on the other hand the level of MDA was significantly increased (p<0.05) in diabetic rats without treatment compared to normal rats (p<0.05) while the level of MDA in diabetic treated groups with the *P. kotschyi* (Table V) were significantly lower (p<0.05) compared to diabetic rats without treatment.

3.7 MORPHOLOGY OF TESTIS

The testis of control or (normal) rats (Figure 1a) exerted different stages in seminiferous elements comprising germ cells, Leydig cells and interstitial cells, which were normal in appearance compared to rats in the diabetic control untreated group. Towards the lumen, the primary spermatocytes, secondary spermatocytes, early spermatids and elongated spermatids were associated with Leydig cells. Mature spermatocytes were also visible in the same region. The diabetic rats without treatment (Figure 1b) showed testicular atrophy, and degeneration in the various stages of spermatogenesis. The basement membrane and tunica propria became thin and disrupted. Spermatogenesis was arrested either at the primary spermatocyte or at the spermatogonial stages. The Leydig cells showed vacuolization and cell debris due to cytolysis. The intercellular spacing became wider, Leydig cells reduced in numbers and the interstitium contained mostly fibroblasts. Diabetic rat treated with the ethanolic roots extract of *Pseudocedrela kotschyi* *P. kotschyi* 250 mgkg⁻¹ (Figure 1c) showed seminiferous tubules atrophy and presence of some germ cells in some tubules. Diabetic rat treated with the ethanolic roots extract of *P. kotschyi* 500 mgkg⁻¹ (Figure 1d) showed that the animals regenerated almost their normal general histology. Most of their seminiferous tubules were close together with regular outlines and narrow interstitium. A few tubules still had regeneration in their germinal epithelium, areas of epithelial separation, and a few sperm cells in their lumina were observed.

4.0 DISCUSSION

Our current data indicate that blood glucose level significantly increased, but body weight gain decreased after injection of ALX into the male rats. Oral administration of ethanolic roots extract of *Pseudocedrela kotschyi* (*P. kotschyi*) into the diabetic male rats at the dose of 250 and 500 mg/kg for 30 days caused the increased of average body weights of the bodies and weight of testis and epididymis, with an increase of semen quantity and motility, other than a decrease in blood glucose level, and an increase of serum testosterone level and the testicular oxidative stress markers as compared with the diabetic group.

It has also been reported that the cytotoxic action of ALX is mediated by the formation of free radicals such as superoxide and catalase radicals [37]. It has been reported that ALX induction in animals increased the level of lipid peroxidation an indication of tissue damage. Sperm plasma membrane has a high content of polyunsaturated fatty acids which is easily susceptible to lipid peroxidation caused by oxidative stress [38-39].

Excessive ROS production that exceeds critical levels can overwhelm all antioxidants defense strategies of spermatozoa and seminal plasma causing oxidative stress that damages the biological membranes in the testes. This in turn may cause the degeneration of the spermatogenic and Leydig cells, which disrupts spermatogenesis and reduces sperm counts [42-43].

Evaluation of SOD, CAT, GPx, lipid peroxidation, as well as GSH content and other antioxidant enzyme activities in biological tissue have been always used as markers for tissue injury and oxidative stress [38, 44-46,52].

In our study, testicular oxidative damage by ALX induction are also exhibited by a significant increase in the activities of antioxidant enzymes, SOD, CAT, GPx and the testicular content of MDA and a significant decrease of GSH as compared with the diabetic group. However, diabetic rats treated with the *Pseudocedrela kotschyi* (*P. kotschyi*) markedly attenuates the oxidative damage by ALX induced in rats. Therefore it is possible to suggest that this extract is safe and might confer protection against ALX induced testicular damage as evidenced by normal levels of antioxidant enzymes and testicular contents in treated diabetic groups.

The extract caused an increase in the weight of the testes, which was accompanied by an increase in the serum levels of testosterone. Similar reports have been made with the extract of *Quassia amara*, *Azadirachta indica*, *Morinda lucida*, *Zingiber officinale* and *Nigella sativa* in rats [7,9-10, 47-48]. The present study shows that injecting of male rats with ALX compound reduced weights of testis and epididymis, testosterone production, sperm motility and count, suggesting a toxic effect of ALX in the cytoarchitecture and functional integrity of testicular tissues. It has been reported that induction of diabetes by high doses of ALX in male testes lead to reduction in testosterone production, suggesting a decrease in the function of both Leydig (testosterone producing cell) and Sertoli (spermatogenesis), which might be due to a reduction in insulin secretion [49-50].

It has been reported that glucose oxidation and utilization are important means by which spermatozoa derives energy for their motility [51]. It has also been reported that testicular weight reduction accompanied by decreased serum testosterone levels in male rats treated with the ALX-induced diabetic rats [53].
Both *Cnidoscolus aconitifolius* and *Nigella sativa* have been demonstrated to possess potent antifertility properties [53,48]. Since all organs of male reproduction are androgen receptor, they serve as indicators of the Leydig cell function or androgen action. Testosterone in association with follicle stimulating hormone normally acts on the seminiferous tubules to initiate and maintain spermatogenesis [54-55].

However, a significant decrease in the epididymal sperm count of rats treated with the extract for 4 weeks was recorded despite the high serum testosterone level. Testosterone is known to be critically involved in the development of sperm cells and derangement results widely in Leydig cell dysfunction and testicular steroidogenic disorder [10].

This study suggests that *Pseudocedrela kotschyi* does not have spermatoxic effects but rather, it could potentially be further investigated for use in the management of the development of diabetes and improved the performance of male reproductive system. In view of these findings, further investigations into the effects of *Pseudocedrela kotschyi* with longer period of higher doses may show clearer features on male reproductive hormones and fertility will be required.

5.0 CONCLUSION

We concluded that administration of ethanolic roots extract of *Pseudocedrela kotschyi* exerted antihyperglycemic and fertility activities in ALX-induced diabetic male rats. Therefore, the oral administration of *Pseudocedrela kotschyi* is of interest because, it is with reversing the negative effects of ALX compounds. It was also shown to be non-toxic and safe for consumption at the doses used in this study. In addition, based on the fact that the possible consumption of ethanolic roots extract of *Pseudocedrela kotschyi* exhibits a potent protection on the testis of laboratory animals induced with ALX, it could be a potential alternative as a therapy to improve the performance of male reproductive system in animals and humans provided that further investigations also support these findings.

COMPETING INTERESTS

Authors have declared that no competing interests exist.

AUTHORS’ CONTRIBUTIONS

This work was carried out in collaboration between all authors. AOO designed the study and performed the statistical analysis. He equally wrote the first draft of the manuscript and undertook the final editing of the paper. OTO wrote the protocol, part of the draft and undertook in the initial editing of the paper. OAO and BJD carried out most of the literature searches while JOO handled the tissue processing for histology and FAF performed the histological analysis. All authors read and approved the final manuscript.

CONSENT

Not applicable.

ETHICAL APPROVAL

All authors hereby declare that “Principles of laboratory animal care” (NIH publication No.
85-23, revised 1985) were followed, as well as specific national laws where applicable. All experiments have been examined and approved by the appropriate ethics committee*. All authors hereby declare that all experiments have been examined and approved by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki.
