

Rhoifolin; A Potent Antiproliferative Effect On Cancer Cell Lines

Omayma A. Eldahshan*

Pharmacognosy Department, Faculty of Pharmacy, Ain shams University, Cairo, Egypt

ABSTRACT

Aims: To investigate the cytotoxic activity of rhoifolin against different cancer cell lines

Study Design: isolation, identification and cytotoxic activity evaluation.

Place and Duration of Study: Faculty of Pharmacy, Ain Shams University and Al-Azhar University, between October, 2010 and January, 2011.

Methodology: Rhoifolin, Apigenin 7-O- β neohesperidoside was isolated in a copious amount from the leaves of *Chorisia crispiflora* (Bombaceae). Its identity was unambiguously confirmed via different spectroscopic methods (UV, ^1H NMR, ^{13}C NMR and HMBC) and Viability assay test was used to evaluate its cytotoxic activity.

Results: It exhibited potent anticancer activities, nearly similar to that of vinblastine, when evaluated against human epidermoid larynx (Hep 2) and human cervical (HeLa) carcinoma cell lines. Promising activities were also obtained against hepatocellular (Hep G2), colon (HCT-116) and fetal human lung fibroblast (MRC-5) carcinoma cell lines. A unique effect of rhoifolin was in having no cytotoxic activity against healthy normal cells (Vero cells) which indicates a high selectivity of the compound selected.

Conclusion: The findings of this study showed that rhoifolin could be used as an ideal anticancer agent. It discriminates between cancerous and non cancerous cell as it kills only the former one. So the side effects which may appear during chemotherapy could be overcome.

Keywords: Roifolin; Chorisia crispiflora; Bombaceae; spectroscopic methods; cytotoxic activity

1. INTRODUCTION

The introduction of active agents derived from nature into the cancer armamentarium has changed the natural history of many types of human cancer. Throughout medical history, novel plant-derived compounds were of great significance to cancer therapy. As examples of these compounds are vinblastine and vincristine; *Catharanthus roseus* family Apocynaceae (Kalidass *et al.*, 2010). Currently, one of the major cancer treatments is chemotherapy. Most of the chemotherapeutic drugs such as vincristine, paclitaxel, and etoposide (ET) cannot discriminate between cancer and non-cancer cells. Many normal cells are also killed during the process of chemotherapy. This nonspecific cytotoxicity damages the patient's immune system and generates many side effects such as neutropenia, vomiting, hair loss, peripheral neurotoxicity, etc. (Perry *et al.*, 1976 and Einzig *et al.*, 1991).

E-mail address: omiahm@hotmail.com

30 Rhoifolin is apigenin 7-O- β neohesperidoside. It was reported that rhoifolin has lots of
31 pharmacological actions. It exerts its anti-diabetic effect through enhanced adiponectin secretion,
32 phosphorylation of insulin receptor- β , and GLUT4 translocation (Rao *et al.*, 2011). It has an
33 antiinflammatory action via multi-level regulation of inflammatory mediators (Eldahshan and Azab,
34 2012). Rhoifolin produced no change in hypoxic pulmonary vasoconstriction, but decreased
35 cardiac output and aortic pressure (Occhiuto and Limardi, 1994).

36
37 Apigenin nucleus is a cancer chemopreventive agent. It inhibits cell proliferation in cancer cell
38 types (Sarkar and Li, 2004). Because of its potential antioxidant, anti-inflammatory, and anti-
39 tumor properties, apigenin is considered as a candidate cancer chemopreventive agent (Birt *et*
40 *al.*, 1996; Birt *et al.*, 1997; Lepley *et al.*, 1996; Ross and Kasum, 2002).

41
42 Apigenin inhibited the growth through an apoptotic pathway in human cervical carcinoma HeLa
43 cells (Zheng *et al.*, 2005). Furthermore, apigenin inhibited A549 lung cancer cell proliferation and
44 vascular endothelial growth factor (VEGF) transcriptional activation in a dose-dependent manner
45 (Ling *et al.*, 2005). However, Kawaii (Kawaii *et al.*, 1999) reported the weak effect of rhoifolin
46 against melanin pigment producing mouse melanoma, human T-cell leukemia, human lung and
47 lymph node metastatic carcinoma cell lines.

48
49 So far, nothing has been documented about the cytotoxic effect of rhoifolin against human
50 epidermoid larynx (Hep 2), human cervical (HeLa), hepatocellular (Hep G2), colon (HCT-116)
51 and fetal human lung fibroblast (MRC-5) carcinoma cell lines, so the antineoplastic activity of this
52 compound was investigated against these types of cancer cell lines. We reported here for the
53 first time the high potent and selective antitumor activity of rhoifolin against several types
54 of cancer cell lines to develop a preliminary building block for the construction of a new anticancer
55 drug.

56

57 2. MATERIALS AND METHODS

58

59 2.1. Plant Material

60 Chorisia leaves were collected from Zoo Garden in Giza, Egypt, 2010 and were authenticated by
61 Prof. Dr Abdel Salam El Noyehy, Prof. of Taxonomy, Faculty of Science, Ain Shams University,
62 Cairo, Egypt. Voucher specimen was deposited in the herbarium of Pharmacognosy Department
63 (voucher specimen number; CCB-73), Faculty of Pharmacy, Ain Shams University, Cairo, Egypt.
64 The leaves were dried in shade and milled to a fine powder.

65

66 2.2. Extraction and Isolation

67 Powder of air dried leaves of *Chorisia crispiflora* (1 kg) was extracted with 70 % ethanol at room
68 temperature. The extract was entirely dried and dissolved in a small amount of water and
69 partitioned with *n*-hexane, ethyl acetate and butanol successively. The aqueous water residue
70 was totally dried and extracted with methanol at 40°C. The methanolic extract upon
71 concentration yielded yellow crystals of rhoifolin (8.3 g). Purification to the crystals was achieved
72 by crystallization.

73 2.3. Instruments and Materials for Phytochemical Investigation

74 Chromatographically pure materials 1 mg each were dissolved in analytically pure methanol next
75 subjected to UV spectroscopic investigation in 4 ml capacity quartz cells 1 cm thick using a Carl
76 Zeiss spectrophotometer PMQ II. AlCl₃, AlCl₃/HCl, fused NaOAc / H₃BO₃ and NaOMe reagents
77 were separately added to the methanolic solution of investigated material and UV measurements
78 were later carried out.

79 The NMR spectra were recorded on a Varian Mercury VX-500 NMR spectrometer. ¹H- spectra
80 ran at 300 MHz and ¹³C- spectra were run at 75.46 MHz in deuterated dimethylsulphoxide (DMSO-
81 *d*₆).

82 Rhoifolin: Apigenin 7-O-β neohesperidoside, C₂₇H₃₀O₁₄, yellow needles, m.p. 250-265°C.

83 IR ν_{max} (KBr): 3388 (OH), 1657 (α, β-unsat. CO), 1605, 1497, and 1488 (arom. C=C), 1249,
84 1178, 1074 (glycosidic C–O) cm⁻¹.

85 UV λ_{max} (log ε) (MeOH): 266 (4.20), 336 (4.30) nm; (MeONa): 267 (4.20), 387 (4.40) nm;
86 (NaOAc): 257 (4.20), 266 (4.20), 391 (4.40) nm, (NaOAc + H₃BO₃): 268 (4.20), 340 (4.30) nm;
87 (AlCl₃): 275 (4.20), 299 (4.10), 350 (4.20), 385 (4.20) nm, (AlCl₃ + HCl): 276 (4.20), 298 (4.10),
88 342 (4.20), 382 (4.10) nm.

89 ¹H-NMR, DMSO-*d*₆ δ ppm: 7.91(2H, d, *J*=8.8 Hz, H-2',6'), 6.92(2H, d, *J*= 8.8 Hz, H-3',5'), 6.84
90 (1H, d, *J*= 2.0 Hz, H-8), 6.80 (1H, s, H-3), 6.33(1H, d, *J*= 2.0 Hz, H-6), 5.08(1H, singlet like, H-
91 1''), 5.20 (1H, d, *J*= 7.3 Hz, H-1''), 1.16(3H, d, *J*=6.3Hz, H-6'').

92 ¹³C-NMR, DMSO-*d*₆ δ ppm: 182.1-C4, 164.4-C2, 162.6-C7, 161.7-C4', 161.1-C5, 157.1-C9,
93 128.7-C2',6', 120.9-C1', 116.2-C-3',5', 105.5-C10, 103.2-C3, 99.4-C6, 94.6-C8, Sugar proton:
94 100.5-C1'', 98.2-C1'', 77.6-C2'', 77.4-C3'', 76.8-C5'', 72.3-C4'', 71.0-C2'', 70.8-C3'', 70.1-
95 C4'', 68.8-C5'', 60.9-C-6'', 18.5-C-CH₃.

96 2.4. Mammalian Cell Lines

97 Vero cells (Normal kidney cells).

98 Carcinoma cell lines: Hep2 (human epidermoid larynx carcinoma cells), HeLa cells (human
99 cervical carcinoma cells), Hep G2 (human hepatocellular carcinoma), **HCT-116** (human colon
100 carcinoma cells) and MRC-5 (fetal human lung fibroblast cells).

101 All cell lines of a well-differentiated carcinoma were obtained from the American Type Culture
102 Collection (ATCC).

103 2.5. Chemical Used

104 Dimethyl sulfoxide (DMSO), crystal violet and trypan blue dye (Sigma, St.Louis, Mo., USA).

105 DMEM, RPMI-1640, FBS, HEPES buffer solution, L-glutamine, gentamycin and 0.25 % Trypsin-
106 EDTA (Bio Whittaker @Lonza, Belgium). Crystal violet stain (1%).

107

108 2.6. Cytotoxicity Evaluation Using Viability Assay

109 Cell toxicity was monitored by determining the effect of the test sample on cell viability through
110 **the viability test** (Vijaya *et al.*, 2004 and Mosmann, 1983).

111

112 3. RESULTS AND DISCUSSION

113

114 3.1. Identification of the Compound

115 Pure material of rhoifolin was obtained as an amorphous light yellow powder, which appeared as
116 a dark purple spot on Paper chromatography (PC) and turned yellow upon exposure to ammonia

117 vapors, under short UV light (254 nm). Confirmation of the compound was achieved through UV
118 shift reagents, ¹HNMR, ¹³CNMR and HMBC correlation (Fig. 1).

119 3.2. Cytotoxic Activity of the Compound

120 The tested compound showed marked toxic effects to the cancerous cell lines. It exerted
121 cytotoxic activity to Hep 2 and HeLa cell lines at IC₅₀ 5.90 and 6.2 μg/mL respectively (Fig. 2 B &
122 C). HepG2 is affected but to a lesser extent by the compound at IC₅₀ 22.6 μg/mL (Fig. 2-D). The
123 least potent activities were to HCT-116 and MRC-5 at IC₅₀ 34.8 and 44.6 μg/mL respectively (Fig.
124 2 E & F).

125 Historically natural products have been an important source of antineoplastic drugs. Sixty
126 percent of currently used antitumor agents are of natural origin, derived from plants, marine
127 organisms and is a useful tool for the discovery of new potential anticancer agents from natural
128 products. One of the important criteria for a therapeutic drug for cancer is to have minimum or no
129 side effects on normal body cells of patients undergoing chemotherapy. This invariably implies
130 that the drug should not only have high potent activity at lower concentrations but also should
131 exhibit a high degree of selectivity.

132 Thus, development of novel selective drugs is an important and challenging task, and
133 understanding the biological differences between normal and cancer cells is essential for
134 achieving this goal.

135 The present *in vitro* study showed the ability of rhoifolin to exhibit a high degree cytotoxic activity
136 to cancerous cells with great selectivity, where, as it is clear, that the compound has no cytotoxic
137 activity against mammalian normal cells (Table 1, Fig 2A).

138 Table 1 showed that the compound of interest exhibited high cytotoxic activity to laryngeal cancer
139 cells, at a very low IC₅₀= 5.9 μg/mL followed by cervical at IC₅₀= 6.2 μg/mL, both are nearly
140 similar to that of vinblastine. Hepatic cell line was also affected but at a lesser extent by the
141 toxicity of rhoifolin at IC₅₀ 22.6 μg/mL. The colon and the fetal human lung fibroblast cell lines are
142 affected at IC₅₀ 34.8 and 44.6 μg/mL respectively.

143 The selectivity index (SI) was defined as the ratio of the IC₅₀ obtained from the experiment on
144 normal cells vs. cancer cells. High selectivity was achieved when the SI was ≥ 3 (Prayong *et al.*,
145 2008). As the Selective index (SI) demonstrates the differential activity of a pure compound, the
146 greater the SI value is, the more selective it is. An SI value less than 2 indicates general toxicity
147 of the pure compound (Koch *et al.*, 2005).

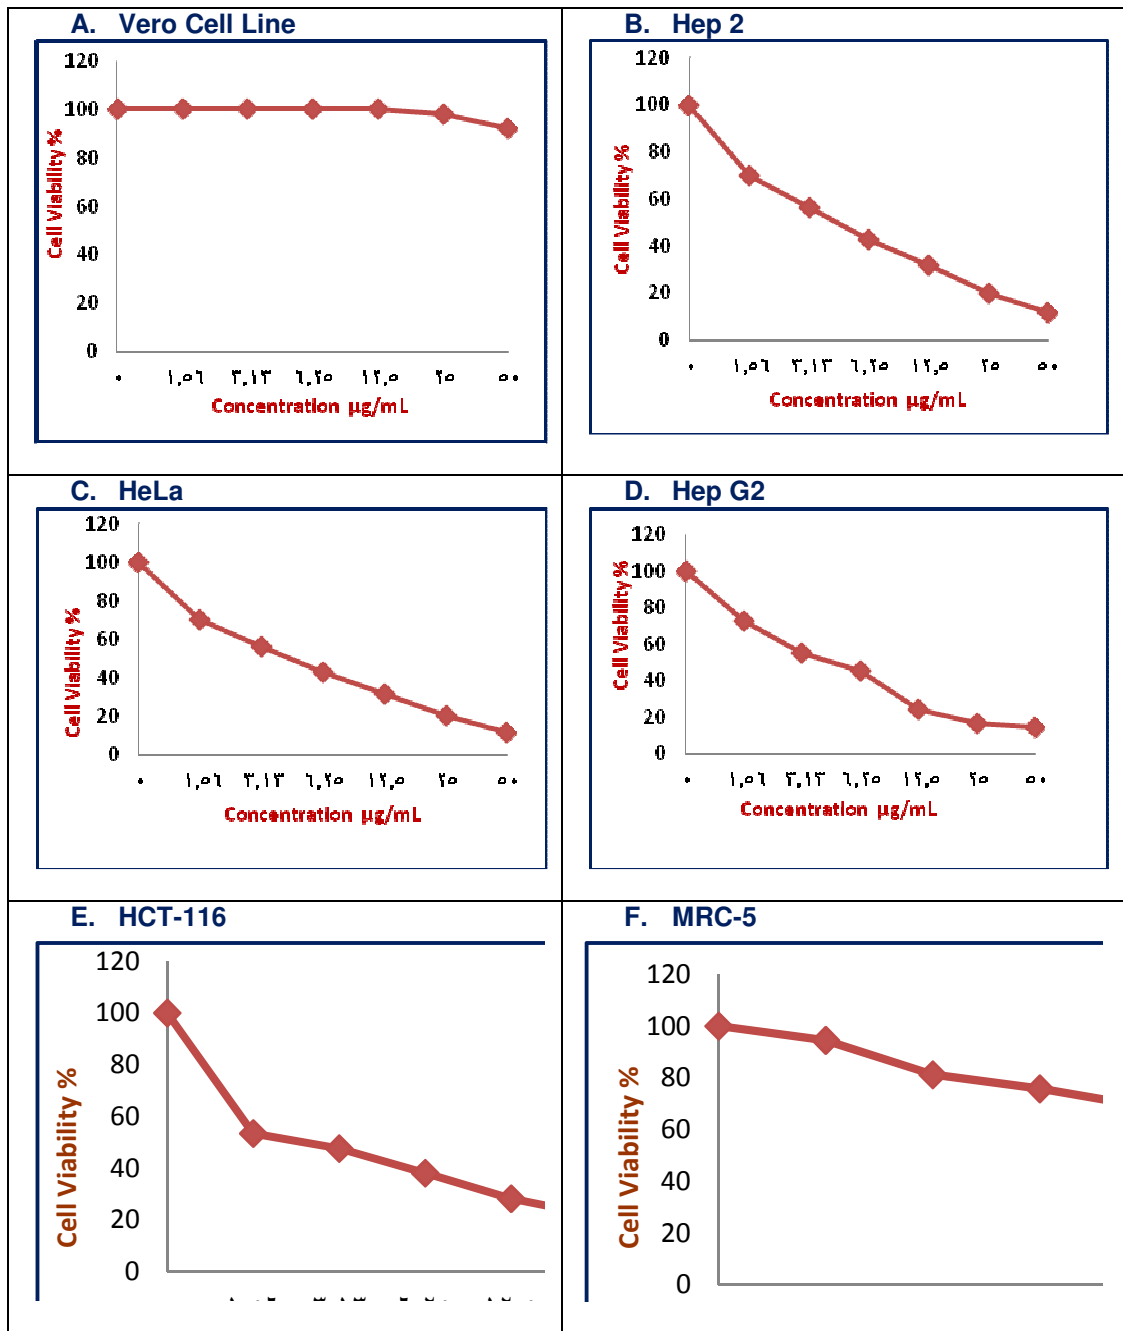

148 Based on this, the SI data shown in Table 2 indicates that rhoifolin exhibits a very high degree of
149 cytotoxic selectivity at SI greater than 8.47 for laryngeal cell lines, followed by 8.06 in cervical and
150 2.21 in hepatic carcinoma cell lines. The other two carcinoma cell lines; colon and fetal human
151 lung fibroblast are of little SI.

198 **4. CONCLUSION**

199

200 Interestingly, this present study, showed the following advantages of rhoifolin:

201 1. Potent cytotoxic effect nearly similar to that of vinblastine which may become a good
202 therapeutic strategy to its use as an antagonist for treatment of this dreaded disease, especially
203 laryngeal, cervical and hepatic cancer.

204 2. It is considered as an ideal antitumor agent to **specific cancerous cells** where it is toxic to
205 malignant with no toxicity to normal cells so it will be a good building unit for a new antitumor drug
206 without side effects.

207 However, currently there are limited numbers of such agents available for clinical use. The
208 mechanisms behind its respective anticancer effect are now under investigation to pave a way to
209 a discovery of a new cancer therapeutic agent.

210
