ABSTRACT
The seeds of Cola nitida were investigated for their anti-diabetic properties. The extracts were obtained by maceration in cold water. Alloxan was used to induce diabetes mellitus in the rats at 180mg/kg body weight and diabetes was confirmed after 48 hours. The Phytochemical analyses of the plants showed the presence of tannin, flavonoid, terpenoid, cardiac-glycoside, and alkaloids. Anthraquinone and saponin were observed to be absent. Cola nitida was also observed to cause a reduction in blood glucose level from 599±0.667mg/dl (diabetic control) to 170±0.577mg/dl (extract treated group). The extract showed a significant (P<0.05) decrease of blood glucose level in alloxan induced diabetic rats. Cola nitida aqueous extract showed a higher level of potency when compared to a known anti-diabetic drug (Glanil).

Key words: Hypoglycemia, diabetes mellitus, phytochemical, Cola nitida

INTRODUCTION
Diabetes mellitus, is a condition in which the body does not produce enough, or properly respond to insulin, a hormone produced in the pancreas. This causes glucose to accumulate in the blood, often leading to various complications. Insulin stimulates the uptake of glucose for energy. (Tierney et al., 2002; Rother, 2007). Type I diabetes- known as juvenile onset or insulin sensitive diabetes, results from the body's failure to produce insulin. Type II diabetes or non insulin dependent diabetes mellitus (NIDDM) which is the more prevalent form may have as its
underlying metabolic causes the combined effects of impairment in the insulin mediated glucose disposal and defective secretion of insulin by the β-cells of the pancreas (Grundy et al., 1999).

Diabetes has been conventionally treated with orthodox medicines that function as hypoglycaemic agents, or insulin production modulators and/or lipoprotein lowering agents (Ogbonnia et al., 2008). Sulfonylurea and metformin are valuable in the treatment for hyperglycaemia in NIDDM but they are often unable to lower glucose concentrations to within the normal range, or to reinstate a normal pattern of glucose homeostasis (Senthilvel et al., 2006). Even when effective glycaemic control is achieved, the use of these drugs is restricted by their pharmacokinetic properties, secondary failure rates and accompanied undesirable effects (El.Nagar et al., 2005; Egwim, 2005). Acute complications including hypoglycemia, diabetic ketoacidosis, or nonketotic hyperosmolar coma may occur if the disease is not adequately controlled. Serious long-term complications include cardiovascular disease, chronic renal failure, retinal damage, which can lead to blindness, several types of nerve damage, and microvascular damage, which may cause erectile dysfunction and poor wound healing. Poor healing of wounds, particularly of the feet, can lead to gangrene, and possibly to amputation (Mailloux et al., 2007). Adequate treatment of diabetes, as well as increased emphasis on blood pressure control and lifestyle factors such as not smoking and maintaining a healthy body weight, may improve the risk profile of most of the chronic complications. In the developed world, diabetes is the most significant cause of adult blindness in the non-elderly and the leading cause of non-traumatic amputation in adults, and diabetic nephropathy is the main illness requiring renal dialysis (Mailloux et al., 2007).

Hypoglycemia, or abnormally low blood glucose, is an acute complication of several diabetes treatments. The patient may become agitated, sweaty, weak and consciousness can be altered or even lost in extreme cases, leading to coma, seizures, or even brain damage and death (Osheke et al., 2014). In patients with diabetes mellitus, this may be caused by several factors, such as too much or incorrectly timed insulin, too much or incorrectly timed exercise (exercise decreases insulin requirements) or not enough food (specifically glucose containing carbohydrates) (Mahdi et al., 2003). Reduced sympathoadrenal responses can cause hypoglycemia unawareness. In many cases (but not all), short-term avoidance of hypoglycemia reverses hypoglycemia.
unawareness in affected patients, although this is easier in theory than in clinical experience (WHO, 1980).

Most of these orthodox medicines are not suitable for use during pregnancy (Senthilvel et al., 2006; Sushruta et al., 2006). Since the therapy is life long, therapeutic agents devoid of side effects would be appreciated and one of such approach is the use of alternative system of medicine comprising herbal products (Pari and Saravanan, 2004). For these reasons, therefore, there is a great need for a search of an acceptable, cheap and safe blood sugar lowering oral hypoglycaemic agents that would be effective in the treatment of diabetes and devoid of serious side effects of the currently used oral hypoglycaemic agents. Cola nitida has been suspected to have hypoglycemic effects though it has not been an area of extensive research (Steward, 2002).

Cola nitida is a genus of about 125 species of trees native to the tropical rainforests of Africa, classified in the family Malvaceae, subfamily Sterculioideae. They are evergreen trees, growing to 20 m tall, with glossy ovoid leaves up to 30 cm long. (Benjamin et al., 1991) It is valued for its caffeine content and stimulant properties. It is also useful for fighting fatigue and stimulating the central nervous system. It contains theobromine, the same stimulant found in green tea (Dewole et al., 2013). The American Medical Association recommends cola nut over other types of stimulants because it is non-habit-forming and does not cause depression (Benjamin et al., 1991). It is also a known diuretic and therefore may help with renal and rheumatic conditions. cola nut helps expand bronchial air passages and therefore is useful for treating conditions like asthma and whooping cough. It also acts as an appetite suppressant and stimulates digestion by activating the production of gastric juices (Christophersen et al., 1991). Due to the information by local herbal healers, this present work therefore, was aimed at determining the hypoglycemic property of aqueous extract of Cola nitida seed on alloxan-induced diabetes mellitus in rats with a view to certify the claim by local herbal healers for the seed’s potency or otherwise.

MATERIALS AND METHODS

Collection and identification of plant material
Cola nitida seeds were bought from Akure, Ondo state of Nigeria and was identified by Mrs. Jemilat Ibrahim a botanist of the Herbarium Unit, National Pharmaceutical Institute of Research and Development (NIPRD) Idu, Abuja Nigeria.

**Experimental animals**
Male albino rats (7-8 weeks old, weighing about 135-150 kg) were purchased from the animal house of University of Jos, Nigeria. The animals were allowed to acclimatize for two weeks prior to commencement of the experiment. They were kept at room temperature and were maintained ad libitum on tap water and growers mash (Vita feeds, Jos, Plateau State Nigeria). They were weighed prior to commencement and termination of the experiment.

**Extraction of plant material**
The seeds were chopped into smaller pieces, dried at room temperature (37°C) for four weeks, and then ground to fine powder, using a blender. The powdered material (20g) was percolated with 100ml of water. It was then filtered and concentrated in a rotary evaporator. The extract obtained was weighed (4.7g) and stored in the refrigerator until when needed.

**Phytochemical screening**
Phytochemical tests were carried out on the aqueous extract and on the powdered specimens using standard procedures to identify the constituents as described by Sofowara (1982); Trease and Evans (1983)

**Test for tannins**
Briefly, 0.5 g of the dried powdered samples was boiled in 20 ml of water in a test tube and then filtered. A few drops of 0.1% ferric chloride was added and observed for brownish green or a blue-black colouration which indicates the presence of tannins.

**Test for saponin**
Briefly, 2 g of the powdered sample was boiled in 20 ml of distilled water in a water bath and filtered. 10ml of the filtrate was mixed with 5 ml of distilled water and shaken vigorously for a stable persistent froth. The frothing was mixed with 3 drops of olive oil and shaken vigorously, then observed for the formation of emulsion.
**Test for flavonoids**

Briefly, three methods were used to determine the presence of flavonoids in the plant sample (Sofowara, 1982). 5 ml of dilute ammonia solution were added to a portion of the aqueous filtrate of each plant extract followed by addition of concentrated $\text{H}_2\text{SO}_4$. A yellow colouration observed in each extract indicated the presence of flavonoids. The yellow colouration disappeared on standing. Few drops of 1% aluminium solution were added to a portion of each filtrate. A yellow colouration was observed indicating the presence of flavonoids. A portion of the powdered plant sample was in each case heated with 10 ml of ethyl acetate over a steam bath for 3 min. The mixture was filtered and 4 ml of the filtrate was shaken with 1 ml of dilute ammonia solution. A yellow colouration was observed indicating a positive test for flavonoids.

**Test for steroids**

Briefly, 2 ml of acetic anhydride was added to 0.5 g ethanolic extract of each sample with 2 ml $\text{H}_2\text{SO}_4$. The colour changed from violet to blue or green in some samples indicating the presence of steroids.

**Test for terpenoids (Salkowski test)**

Exactly 5 ml of each extract was mixed in 2 ml of chloroform, and concentrated $\text{H}_2\text{SO}_4$ (3 ml) was carefully added to form a layer. A reddish brown colouration of the interface was formed to show positive results for the presence of terpenoids.

**Test for cardiac glycosides (Keller-Killani test)**

Briefly, 5 ml of each extracts was treated with 2 ml of glacial acetic acid containing one drop of ferric chloride solution. This was underlayed with 1 ml of concentrated sulphuric acid. A brown ring of the interface indicates a deoxysugar characteristic of cardenolides. A violet ring may appear below the brown ring, while in the acetic acid layer, a greenish ring may form just gradually throughout thin layer.

**Test for Anthraquinones**

Briefly, 0.5 g of the extract was boiled with 10 ml of sulphuric acid and filtered while hot. The filtrate was shaken with 5 ml of chloroform. The chloroform layer was pipette into another test tube and 1 ml of dilute ammonia was added. The resulting solution was observed for colour change (pink, violet or red colour).
Quantitative determination of the chemical constituent

Preparation of fat free sample

Briefly, 2 g of the sample were defatted with 100 ml of diethyl ether using a soxhlet apparatus for 2 hrs.

Determination of total phenols by spectrophotometric method

This was done according to the Folin and Ciocalteau’s method as described by Ayoola et al., (2008). The fat free sample was boiled with 50 ml of ether for the extraction of the phenolic component for 15 min. 5 ml of the extract was pipetted into a 50 ml flask, then 10 ml of distilled water was added. 2 ml of ammonium hydroxide solution and 5 ml of concentrated amylalcohol were also added. The samples were made up to mark and left to react for 30 min for colour development. This was measured at 505 nm.

Alkaloid determination using Harborne (1973) method

Briefly, 5 g of the sample was weighed into a 250 ml beaker and 200 ml of 10% acetic acid in ethanol was added and covered and allowed to stand for 4 h. This was filtered and the extract was concentrated on a waterbath to one-quarter of the original volume. Concentrated ammonium hydroxide was added dropwise to the extract until the precipitation was complete. The whole solution was allowed to settle and the precipitate was collected and washed with dilute ammonium hydroxide and then filtered. The residue is the alkaloid, which was dried and weighed.

Tannin determination by Markkar and Goodchild (1996) method

Briefly, 500 mg of the sample was weighed into a 50 ml plastic bottle. 50 ml of distilled water was added and shaken for 1 h in a mechanical shaker. This was filterate into a 50 ml volumetric flask and made up to the mark. Then 5 ml of the filtered was pipetted out into a test tube and mixed with 2 ml of 0.1 M FeCl$_3$ in 0.1 N HCl and 0.008 M potassium ferrocyanide. The absorbance was measured at 120 nm within 10 min.

Saponin determination:

The method used was that of Obadoni and Ochuko (2001). The samples were ground and 20 g of each were put into a conical flask and 100 cm$^3$ of 20% aqueous ethanol were added. The samples were heated over a hot water bath for 4h with continuous stirring at about 55°C. The mixture was filtered and the residue re-extracted with another 200 ml 20% ethanol. The combined extracts were reduced to 40 ml over water bath at about 90°C. The concentrate was
transferred into a 250 ml separatory funnel and 20 ml of diethyl ether was added and shaken vigorously. The aqueous layer was recovered while the ether layer was discarded. The purification process was repeated. 60 ml of n-butanol was added. The combined n-butanol extracts were washed twice with 10 ml of 5% aqueous sodium chloride. The remaining solution was heated in a waterbath. After evaporation the samples were dried in the oven to a constant weight; the saponin content was calculated as percentage.

**Flavonoid determination by the method of Pham et al., (2007)**

Exactly, 10 g of the plant sample was extracted repeatedly with 100 ml of 80% aqueous methanol at room temperature. The whole solution was filtered through whatman filter paper No 42 (125 mm). The filtrate was later transferred into a crucible and evaporated into dryness over a water bath and weighed to a constant weight.

**Induction of diabetes and experimental grouping**

Thirty (30) albino rats of both sexes of average weight of 145 kg were randomly divided into six groups of five rats each. Group A, served as the normal control fed with the standard animal feed and water only. Group B, C, D, E and F were administered freshly prepared alloxan monohydrate solution dissolved in normal saline (120mg/kg) intraperitoneally. Blood sample from experimental rats were collected from the tail vein after over-night fasting and hyperglycemia was confirmed forty-eight (48) hours after induction by quantitative determination of blood glucose levels as described by Bowman and Rand (1985), using one touch basic glucose monitoring system. Thereafter, group B received no treatment as it was the diabetic control. Group C was treated with Glanil (standard diabetes mellitus drug, 1mg/kg) while groups D, E and F were treated with aqueous extract of *Cola nitida* seed for fourteen (14) days (40, 80 and 120 mg/kg respectively) before sacrifice. The study was carried out according to the specifications of the Bingham University Animal Ethical Research Committee.

**Animal sacrifice**

Animals were sacrificed after light chloroform anesthesia and whole blood was collected and allowed to clot before it was centrifuged to obtain serum. All serum samples were kept in eppendorf tubes and stored at -20 °C for biochemical analysis.
DETERMINATION OF BLOOD PARAMETERS

Determination of Serum Cholesterol

Cholesterol was determined spectrophotomerically at 570nm using assay kit (Randox Laboratories Ltd, UK) following enzymatic hydrolysis and oxidation as described by Witte et al., (1974). Three test tubes were labeled test, standard and blank. To each of these test tubes was added 0.2ml of serum, cholesterol standard and distilled water respectively. Thereafter, 5.0ml acetic acid-acetic anhydride reagent was added to each of the test tubes and the solution were thoroughly mixed, and then allowed to stand for a period of 5 minutes. 0.1ml of concentrated sulphuric acid was added alongside to each of the tube, mixed thoroughly and kept in cold water for a period of 10 minutes. The absorbance was then read against the blank. Concentration of the test sample was calculated as follows:

\[
\text{Concentration of test} = \frac{A_{(test)} \times \text{Conc.(std)}}{A_{(std)}}
\]

Determination of liver function parameters

Aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were determined colorimetrically at 540nm using Randox assay kits based on the principle first described by Reitman and Frankel (1957).

Also, using the Randox kit, the colorimetric assay method for conjugated bilirubin employed involved reaction with diazotized sulphanilic acid in alkaline medium to form a blue complex, while total bilirubin was determined in the presence of caffeine, which releases albumin-bound bilirubin that then reacts with diazotized suphanilic acid as described by Jendrassik and Grof, (1938).

Statistical Analysis

Data were expressed as mean ± SEM. The data obtained were analyzed using one-way analysis of variance (ANOVA). Tukey’s multiple comparison post-hoc test was used to determine the level of significance between control and experimental groups. Values of P < 0.05 were considered as significant.
RESULT

The results of the phytochemical analysis of *Cola nitida* seeds extract show the presence of some phytochemical compounds and the quantities available as listed in Table 1.

**Table 1:** Qualitative and quantitative analysis of the phytochemical constituents of *Cola nitida* seed

### DISCUSSION

As a result of the side effects of orthodox drugs used in treatment of diabetes mellitus, attention has been focused on the use of plants and herbal remedies believed to be safer and devoid of serious side effects as alternatives in the treatment of diabetes. The potency of the aqueous extract of *Cola nitida* was measured in terms of reduction in blood glucose level. There was a significant (P<0.05) decrease in blood glucose levels, after 14 days of oral administration of the aqueous extracts of in the alloxan-induced diabetic rats. In Comparison with a known anti-diabetic drug Glanil, *Cola nitida* showed a reduction in blood glucose of 26.04% after 24hrs of treatment as shown in Table 2. The major goal in treating diabetes mellitus is controlling elevated blood sugar (glucose) without causing abnormally low levels of blood sugar (Mooradian, 1996). The results in this study are in partial agreement with Mooradian (1996). It can be observed that the blood glucose level of the extract treated group at a dose of 120mg/kg was at the end of the 14 days of the experiment showed hypoglycemic properties (Table 2). *Cola nitida* has hypoglycemic properties depending on the administered dosages.

The extracts showed to be effective in decreasing plasma glucose levels on the diabetic rats by decreasing blood glycaemia the risk of other disease complications associated with people suffering with diabetes (Ogbonnia *et al.*, 2010). The effective lowering of blood sugar level demonstrated by this extracts supports its local use as a hypoglycaemic agent. From Table 3, the extracts significantly (P<0.05) reduced the cholesterol levels in the groups treated with extract. Alloxan-induced diabetes mellitus in rats caused a significant (P<0.05) increase in the serum cholesterol levels. The high level of cholesterol observed in the diabetic control rats is enough to
predispose people to atherosclerosis. This is in accordance with studies carried out in streptozotocin treated animals by Nakayama and Nagakawa (1977).

The hepatic and cardiac tissues release AST and ALT and the elevation of plasma concentrations of these enzymes is an indicator of hepatic and cardiac damage (Crook, 2006). The decrease in ALT and AST levels in the diabetic animals treated with different doses of the extract (Table 5) implied that the extract at the doses used did not produce any harmful effects on either the cardiac or the hepatic tissues and also, have protected or emlorated the cell membrane from the harmful effect of alloxan. However, in the untreated diabetic rats, the two enzymes showed significant increase which suggested that hepatic and cardiac problems may have occurred (Table 5).

There was a significant increase in total bilirubin concentration in the diabetic control rats, following induction of alloxan after 48hrs. However, administration of *Cola nitida* aqueous extracts produced a decrease in bilirubin concentration after 14 days of treatment. Among the endogenous compounds, the end products of haem metabolism, bilirubin, is the most extensively studied substrate of UGTs (Clark and Burchell, 1994). The observed elevated bilirubin in the serum of the alloxan-induced diabetic rats in this study could have been due to suppression of bilirubin glucuronidation. The fact that the extract caused a reduction in the serum level of bilirubin as observed in this study suggests that the extract has the potential to protect the red blood cells from damage.

**CONCLUSION**

The study showed that aqueous extracts of *Cola nitida* significantly (P<0.05) reduced the elevated levels of blood glucose, cholesterol, bilirubin, AST and ALT in diabetic treated rats. The study also revealed that the extract at doses investigated did not provoke toxic effects to the animals. Due to the above mentioned roles, *Cola nitida* possess hypoglycemic property and the claim by the local herbal healers for the seed’s potency is clarified.
